[28] A method which permits the determination of the halogen which takes part in substitution as well as addition reactions. See Carleton Ellis, "The Chemistry of Petroleum Derivatives," The Chemical Catalog Co., Inc., New York, 1934.

When styrene was hydrogenated using a palladium catalyst, only the side chain was affected; however, in the presence of a platinum catalyst the reaction resulted in the formation of ethylcyclohexane.[29]

ESTIMATION OF AROMATIC HYDROCARBONS IN PETROLEUM DISTILLATES

Among the hydrocarbons which occur in petroleum, aromatics are of particular interest because of their high octane rating (Chapter 44), and many procedures have been suggested for their determination.[30] One depends upon the sulphonation of aromatics by the action of 98 to 100 per cent sulphuric acid.[31] In most cases it has been found that benzene is somewhat difficult to remove completely and quantitatively, although its homologues are more readily sulphonated.[32] Virobyantz[33] has proposed that a portion of the aromatic compounds, which are removed by agitating a distillate with 97 to 99 per cent sulphuric acid for five hours, be recovered by diluting the separated acid solution with an equal volume of water and distilling with steam superheated to 200 or 210°C. Between 50 and 90 per cent of the compounds are said to be regained by this method.

In most procedures involving the use of sulphuric acid, any olefins present in the sample under investigation are either eliminated by treatment with a more dilute acid than that necessary to sulphonate aromatics, or are removed simultaneously with aromatics. However, Vlugter[34] has suggested that the alkenes be hydrogenated selectively in the presence of a specially prepared molybdenum catalyst at 300°C. The aromatics can then be determined in the usual way with sulphuric acid.

Nitration, using nitric and sulphuric acids or nitric acid alone, has been recommended as a method for the estimation of aromatic hydrocarbons. Olefins, when present, are first removed by shaking the gasoline with 85 per cent sulphuric acid. Twenty cc. of the olefin-free sample are then agitated with a nitrating mixture in a 200 cc. round-bottomed flask provided with a graduated neck. Care is taken to insure against excessive rise in temperature. The loss in volume gives the aromatic content of the gasoline. If this is greater than 20 per cent, the original gasoline must be diluted with an aromatic-free distillate before carrying out the determination.[35]

Dobryanskiĭ and Tikhonov-Dubrovskiĭ[36] have outlined a procedure which depends upon reaction with trinitrophenol. Naphthalene has been determined by a somewhat similar procedure.[37] A 0.7 per cent solution of picric acid is placed in each of three wash bottles connected in series. The sample to be tested is placed in the first bottle which is cooled by cold water. The other bottles are maintained at 0°C. by ice baths. A slow stream of air passes through the apparatus until the gasoline has been completely removed from all three containers. The naphthalene, which forms a molecular compound with picric acid, is then determined in the usual way.[38]

---

[29] Using a nickel catalyst, H. I. Waterman and C. van Vlodrop (*Rec. trav. chim.*, 1936, **55**, 401) have shown that peanut oil and naphthalene are hydrogenated simultaneously at atmospheric pressure and 180°C.

Under some conditions, oxidation of side-chains on aromatic hydrocarbons may be used in the analysis of the latter.[39] Reaction may be effected either with chromic acid or a permanganate. Since the oxidation of ortho-substituted dialkyl benzenes with chromic acid may result in breaking the ring structure, it is usually better to substitute this agent by alkaline permanganate.[40]

Aromatic and olefin hydrocarbons may be separated from naphthenes and paraffins by filtration through silica gel.[41] The extent to which the removal proceeds depends largely upon the composition of the sample, as well as the precise compounds involved. It has been noted that considerable loss results in attempting to recover the adsorbed hydrocarbons by distillation from the adsorbing medium.

Estimation of Paraffin Wax. The paraffinic hydrocarbons, together with the cycloparaffins or naphthenes, form the major constituents of petroleum oils. For that reason, determination of these hydrocarbons, except in certain isolated cases, is not very common. It is, however, sometimes necessary to determine the mixture of solid hydrocarbons (often simply called "paraffin") which are dissolved in oil.[42] The sample is dissolved in a solvent, such as ether, and the paraffin precipitated by the addition of a solution consisting of equal volumes of ether and alcohol or of chloroform and cresol and cooling to —21°C. In some instances, the liquid portion (of the specimen) which boils up to about 280°C. is removed by distillation at 30 mm. pressure. Asphaltic bodies may be extracted by treating a sample of the oil in gasoline with a bleaching earth.[43] A solution of 3 parts ethyl acetate and 1 part alcohol has also been recommended for removing oil from paraffin.[44]

The waxes in an asphalt may be determined by first extracting with gasoline, and then dissolving the residue in warm pyridine. On cooling the latter solution to 0°C. the paraffin wax crystallizes out. It is filtered and washed with pyridine. It is then dissolved in benzene for further treatment with activated carbon and clay to eliminate any entrained asphalt. After the latter operation the paraffin is crystallized, washed and dried.[45]

In one method for estimation of asphalt and paraffin in a sample of crude petroleum, a 2-3 g. portion in a weighed flask is extracted with boiling acetone, leaving an asphaltic residue which is then weighed.[46] The acetone extract is cooled to —20°C. to precipitate wax, which is filtered, redissolved in hot benzene, and the latter subsequently evaporated. The wax may then be weighed.

TESTS FOR SULPHUR AND SULPHUR COMPOUNDS

Practically all types of sulphur compounds have been found in crude petroleum or its distillates, though the proportions of such derivatives vary in oils from different sources. Their presence is considered undesirable because of their unpleasant odor (particularly mercaptans or thiols) and also because on oxidation they give rise to substances held to be corrosive (largely sulphur dioxide). The proportion of sulphur in motor fuels in amounts greater than 0.10 per cent is thought by some to cause excessive attack on the motor because of the formation of sulphur dioxide during combustion.[47] The usual tests for sulphur and its compounds in petroleum distinguish between elemental sulphur, hydrogen sulphide, sulphur dioxide and mercaptans, all of which are considered to be particularly nocuous, and the other sulphur-containing compounds which are classed as "residual" sulphur and may be comparatively inoffensive. Sentzov and Chadaeva[48] have noted that elemental sulphur is the most corrosive form of this element. Hydrogen sulphide and mercaptans are also said to be corrosive, although to a lesser extent, but sulphides, disulphides and thiophenes may be considered to be innocuous.

Elemental Sulphur. One procedure commonly employed consists in keeping a copper strip in contact with the petroleum distillate 3 hours at a temperature of 122°F.[49] A discoloration of the strip indicates the presence of elemental sulphur. Alexandrov[50] recommends a temperature of 150°C. and a period of 15 minutes. Operations may be carried out under a reflux condenser. It has been suggested that the copper strip be cleaned by treatment with 5 per cent aqueous ammonia and then oxalic acid.[51]

Another test used in some cases depends upon the reaction of mercury with sulphur. A small proportion of hydrochloric acid is also added to coagulate the sulphide formed. The sulphide is oxidized during digestion with hydrochloric acid by the addition of a small amount of potassium perchlorate. Barium sulphate is then precipitated and weighed. This method has been used by Gabriel'yantz and Artem'eva[52] for the determination of free sulphur in the distillates from Grozny asphalt-base and Baku crude oils. A modification developed by Pieters and his co-workers[53] consists in decomposing the mercuric sulphide with hydrochloric acid and absorbing the liberated hydrogen sulphide in aqueous cadmium acetate. The sulphur was then determined by iodimetry. The results were said to be identical with those obtained using sodium hydroxide and hydrogen peroxide for oxidation of the sulphide.

A rapid determination of sulphur, said to be applicable to the control of doctor sweetening processes, has been developed.[54] In the determination a known quantity of butyl mercaptan in naphtha is added to the gasoline under analysis. The mixture is then agitated with doctor solution until complete reaction of the sulphur and the added mercaptan has occurred. Since the excess mercaptan is now present as lead mercaptide, it is restored to the original mercaptan by dilute sulphuric acid. The gasoline is then washed with acidified cadmium chloride solution (to remove hydrogen sulphide) and titrated with silver nitrate solution[55] to determine the excess mercaptan. The used mercaptan, obtained by difference, permits a calculation of the free sulphur content of the original gasoline.

---

In another method the free sulphur is converted to mercaptans by the action of hydrogen, and determined as mercaptans.[56] The apparatus (Fig. 288) consists of a flask for converting the sulphur, a condenser, gasoline trap and gas washing bottle containing ammoniacal cadmium chloride. The distillate under analysis is placed, together with reduced iron, in the reaction flask, and hydrochloric acid slowly added. The liberated hydrogen reacts with sulphur to form mercaptans. The latter are conducted to the gas bottle, where the hydrosulphides are determined iodimetrically.

Mercaptans. The presence of these compounds in gasoline or kerosene is indicated by the doctor test (using sodium plumbite). This is said to detect methyl, butyl and heptyl mercaptans in concentrations equivalent to 0.002, 0.0002 and 0.00009 per cent of sulphur, respectively.[57] Berger[58] determines the mercaptan content of a gasoline by titration with an aqueous solution of a copper salt. This reagent is made by dissolving 3.91 g. of copper sulphate in 300 cc. of water, chilling, precipitating completely with cold sodium hydroxide (5°Bé. gravity), and finally dissolving the precipitated cupric hydroxide by the addition of cold ammonium hydroxide. The solution is then diluted to 1 liter. It must be kept ice-cold throughout the preparation. Titration is carried out by adding 1 cc. portions of the test solution to 100 cc. of sour gasoline (free from hydrogen sulphide) in a 250 cc. separatory funnel until the blue color of the aqueous layer no longer disappears.

A somewhat different method for the determination of thiols consists in oxidizing them with cupric chloride and estimating the cuprous chloride formed by means of potassium permanganate.[59] Bond[60] has described the titration of mercaptans in gasoline in which a standard solution of copper oleate is used. The solution is made up in kerosene and contains about 4 g. of copper per liter. The end point is a pale green color, which is said to be visible even in the presence of considerable precipitate. The method was found to precipitate mercaptans and hydrogen sulphide, but not to be influenced by the presence of carbon disulphide, organic disulphides or octene. Peroxides, which might develop in the copper oleate solution through oxidation, were injurious to the accuracy of the results. A comparison of this test with the silver nitrate method of Borgstrom and Reid[61] and with an iodimetric method showed that the copper oleate titration gave fairly accurate results.

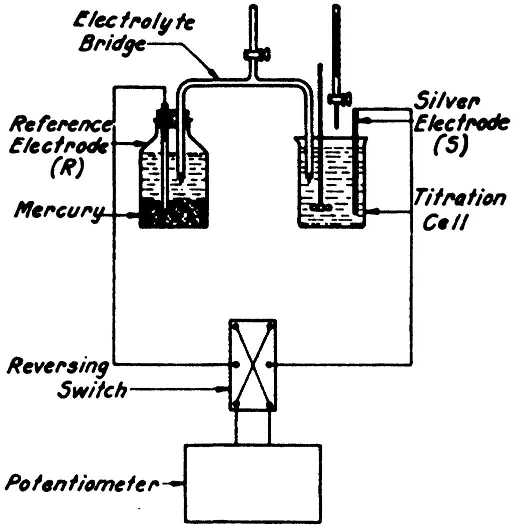

FIG. 289. Diagram of Apparatus for Potentiometric Determination of Mercaptans. (M. W. Tamele and L. B. Ryland)

Courtesy Industrial and Engineering Chemistry

The silver nitrate method, which is similar to Volhard's well-known procedure for the determination of soluble halides,[62] has been modified by different workers. Thus, Malisoff and Anding[63] have recommended the addition of methanol to the solution to minimize the tendency to form emulsions. This was also found to shorten the time required for shaking and washing the precipitate. A source of error has always been the silver adsorbed and occluded by the precipitated silver mercaptide. Malisoff and Anding decreased this somewhat, but the potentiometric method described by Tamele and Ryland[64] is said to give even better results. The procedure is briefly: Add the sample to 50 cc. of approximately 0.1*N* sodium acetate in 96 per cent ethyl alcohol. This solution is part of the silver half-cell of the cell:

−Ag	0.1*N* sodium acetate in alcohol	0.1*N* sodium acetate in alcohol	+Hg

The apparatus recommended is shown in Fig. 289. The e.m.f. of the cell before addition of the sample is approximately —0.070 volts (silver being the negative electrode). If mercaptans are in the liquid under investigation, then the potential of the silver electrode becomes about —0.380 volts. A standard solution (about 0.01*N*) of silver nitrate in 2-propanol is added slowly and the changes in e.m.f. recorded. A sudden drop in the negative potential occurs at the end point. When the e.m.f. is plotted against the volume of standard solution used, a curve, such as that shown in Fig. 290, is obtained. Tamele and Ryland observed that the accuracy of their procedure was not greatly affected by the presence of substances which react with silver nitrate, such as chlorides, because of the extreme insolubility of the silver mercaptides. Peroxides, which were found to vitiate the results of the copper oleate titration, did not influence the potentiometric determination to any appreciable extent. It was necessary, however, to remove elemental sulphur and hydrogen sulphide from the sample.

The presence of the alkyl thiols and thioethers may be shown by the use of the sodium nitroprusside test.[65] This test is ordinarily carried out in the presence of sodium hydroxide. Alkyl sulphides, such as methyl, ethyl, propyl, butyl and amyl sulphides, are said to give violet colorations. Thiophenol gives a reaction only when aqueous ammonia is employed as the alkali. Aryl and aralkyl sulphides do not respond to this test.

Total Sulphur. Determination of the total sulphur content of a petroleum fraction is effected in either of two ways. For the analysis of fairly volatile fractions, such as kerosene and petroleum naphtha, the lamp method[66] is widely used. An oxygen-bomb method[67] has been adopted for non-volatile fractions.

The apparatus for sulphur analysis by the lamp method consists of a 25 to 35 ml. Erlenmeyer flask fitted with a wick, chimney, absorbing bulbs and spray trap[68] as shown in Fig. 291. The procedure is to place a sample of gasoline in the small flask. The wick is cut to the desired length and the lamp and contents weighed. The sample is burned and the vapors drawn by a slight suction through the absorbing bulbs which contain 10 cc. of standard sodium carbonate (3.306 g. per liter)

solution. The time required for burning is from 1 to 1.5 hours, and the oil should be consumed at the rate of about 2 to 2.5 g. per hour. At the end of this time the portion of the unreacted sodium carbonate is determined by titration with dilute hydrochloric acid (2.275 g. per liter). A blank is run at the same time as the sample but using sulphur-free alcohol as the fuel. The results are calculated according to the formula:

$$\text{Per cent sulphur} = \frac{(\text{ml. HCl for blank}) - (\text{ml. HCl for sample})}{(\text{Grams of oil burned}) \times 10}$$

Many modifications of the lamp method have been proposed by various investigators for improving different features. For example, Heinze and Schmeling[69] suggested using a spiral glass coil for the absorption of products of combustion. Their apparatus is said to remove sulphur dioxide quantitatively from a gas stream flowing at the rate of 3 liters per minute. Chernov and Sobolev[70] recommended admitting oxygen with air (after purifying the latter) during burning of the sample. Heusler[71] found that a solution of potassium permanganate could be used for the absorption of oxides of sulphur which were afterwards estimated as sulphates. According to Engler,[72] a solution of bromine in potassium hydroxide or carbonate may be substituted for potassium permanganate. Schulz[73] absorbed the sulphur oxides in hydrogen peroxide and titrated the resulting sulphuric acid. A similar method has been used in the determination of sulphur in benzene.[74] Another absorbing agent, employed by Orlov and Broun,[75] consists of a solution of potassium dichromate and hydrochloric acid.

The oxygen-bomb method for the determination of sulphur in petroleum fractions heavier than illuminating oils consists essentially in burning the sample in an atmosphere of oxygen and precipitating the sulphuric acid formed, as barium sulphate.[76] The procedure is: Place 20 cc. of water in the bottom of the bomb. The sample (from 0.6 to 0.8 g.) of oil is placed in the weighed oil cup, and the latter put in the bomb. The ignition mechanism (an electrically heated wire) is arranged and the bomb closed. Oxygen is admitted under pressure of from 25 to 40 atmospheres. The bomb is put in a pail of water with the ignition leads attached and the sample ignited. The bomb is allowed to stand for 10 minutes before the internal pressure is released, after which it is washed out and the sulphate precipitated from the washings in the usual way with barium chloride. The weighed amount of barium sulphate, after ignition, is used to calculate the results:

$$\text{Percentage of sulphur} = \frac{\text{Grams of } BaSO_4 \times 13.734}{\text{Grams of oil used}}$$

[76] R. C. Griffin (*Ind. Eng. Chem., Anal. Ed.*, 1929, **1**, 167; *Chem. Abs.*, 1929, **23**, 4382; *Brit. Chem. Abs.* **B**, 1929, 768) has reported that the oxidation of sulphur compounds in a bomb converts part of them to sulphonic acids which are not precipitated by barium chloride. However, he found that this sulphur could be recovered by refluxing the filtrate (from the barium sulphate precipitation) with hydrochloric acid. K. Weisselberg (*Petroleum Z.*, 1934, **30** (33), 1; *Chem. Abs.*, 1935, **29**, 1032) noted, on the other hand, that low results for sulphur by this method were due to the loss of sulphur dioxide. He overcame this trouble by the addition of 0.05 g. of ammonium nitrate to the bomb before ignition of the sample. E. Graefe (*Petroleum Z.*, 1934, **30** (38), 2; *Brit. Chem. Abs.* **B**, 1934, 1045) has corroborated Weisselberg's results, but he suggests that a solution of sodium peroxide be used in the bomb for absorbing the oxides of sulphur.

Gavrilenko and Rabinovich[77] modified this general method in such a way that the sulphur is determined by an iodimetric titration rather than gravimetrically. From 12 to 15 cc. of 10 per cent sodium or potassium hydroxide are put into the bomb before ignition. After the sample has been burned, the bomb is washed out with water and 7 to 8 cc. of hydrogen peroxide added to the rinsings. The solution is acidified with hydrochloric acid and then made alkaline with ammonium hydroxide. This is to precipitate iron and aluminum as phosphates (if phosphorus were present in the sample) or hydroxides. The precipitate is filtered and the filtrate acidified with hydrochloric acid and boiled for 5 minutes with a mixture of barium chloride and potassium chromate. The solution is cooled, diluted to a known volume with distilled water, mixed thoroughly and filtered. An aliquot portion (100 cc.) is treated with 3 to 4 g. of potassium iodide in water and 15 cc. of hydrochloric acid. The free iodine is titrated with $0.05N$ sodium thiosulphate (1 cc. is equivalent to 0.000535 g. sulphur). The end point is a change from blue to green (starch indicator).

Besides the two general methods mentioned above for the estimation of sulphur, there are several others which are of interest. For example, the procedure which was first used by Chabley[78] for the determination of halogen in organic compounds has been modified by Sowa, Arcadi and Nieuwland[79] so that sulphur may be determined quantitatively. Dissolve 0.1 g. of the substance in 175 cc. of liquid ammonia, and add metallic sodium until there is a permanent blue color. The resulting solution is then evaporated to 25 cc., 3 to 5 g. of ammonium chloride added and the mixture evaporated to dryness. The residue is dissolved in water, oxidized by sodium peroxide and the sulphur precipitated as barium sulphate. This method is said to be accurate and of general applicability.

Dittrich[80] proposed heating benzine with mercury, aluminum foil and hydrochloric acid. The operation liberates the sulphur as hydrogen sulphide. The latter is then absorbed and titrated with a standard solution of cupric sulphate. The Holthaus method[81] for the determination of sulphur in steel has been adapted for use in the analysis of mineral oil.[82] Combustion is carried out by passing dry oxygen over the sample (heated first to 450-650°C. and finally to 1000-1150°C.) in an electric furnace. The products of oxidation are taken up in a solution of hydrogen peroxide and titrated. A procedure by which the per cent of the various types of sulphur compounds present may be estimated has been recommended by Dubrisay.[83] The method is very similar to that used in determining the corrosiveness of a fuel. Highly polished strips of silver and copper are placed in the liquid. The extent to which these strips are discolored at the end of 48 hours is said to show the amounts of various types of sulphur compounds which are in the fuel. The absence of any effect shows that there is less than 0.001 per cent free sulphur, hydrogen sulphide or alkyl sulphides, less than 0.1 and 0.2 per cent of thiophene and carbon disulphide, respectively. Discoloration of the copper but not the silver shows the presence of free sulphur, neutral sulphides, thiophene or carbon disulphide, whereas the discoloration of silver shows the presence of mercaptans or hydrogen sulphide. Grote and Krekeler[84] have outlined an analytical procedure for the determination of sulphur and halogens in volatile, combustible substances. The method is to volatilize the sample in one portion of a glass tube and then pass it through a highly heated zone (separated from the rest of the tube by porous quartz discs) where it is burned. The products are absorbed in a specially designed absorption bulb, and the sulphate determined either titrimetrically or gravimetrically.[85]

COLOR TESTS

The methods which have been proposed for determining the color of various petroleum distillates may be divided into three general classes. These are: First a given thickness of the oil is matched against one of a set of standards, either glass or liquid. This is exemplified by the Lovibond Tintometer or the Union Colorimeter. In the second class are those tests in which a variable thickness of oil is matched against a standard color disk, as in the Saybolt Chromometer. The third class includes those tests in which the fraction of light absorbed by a specified thickness of oil is determined photometrically. The method described by Story and Kalichevsky[86] is an example. Koetschau[87] has recommended the use of a Zeiss-

[85] W. M. Malisoff (*Ind. Eng. Chem., Anal. Ed.*, 1935, **7**, 428; *Chem. Abs.*, 1936, **30**, 48) has found that chlorine in organic compounds may be determined by much the same procedure as the standard lamp test for sulphur.

Pulfrich photometer in determining the color of lubricating oils and motor fuels. On the other hand, Bolton and Williams[88] have recommended that the percentage of light transmitted through a 1-inch cell containing the oil may be determined using a photoelectric cell and a galvanometer to measure the current generated. The procedure is to measure the light transmitted when the cell is empty and when it contains the oil. The percentage of light transmitted is defined as 100 times the ratio of the latter to the former. Care must be exercised to exclude all infra-red radiation, as the photoelectric cell is very sensitive to light of long wave length. Results obtained by this procedure were found to be roughly related to Lovibond units (as determined by use of a Lovibond Tintometer).

Ferris and McIlvain[89] measure the depth of oil (or a solution of it) which has the same optical density as the standard filter with which the sample is compared. If R is the depth of oil or solution in mm., N the number of dilutions in a 1:10 ratio, and D the optical density of the neutral filter,[90] then the optical density color is:

$$\frac{10^3 D \times 10^N}{R}$$

The comparison of the sample and filter is carried out using green light which is obtained by interposing a glass cell containing a solution of cupric chloride dihydrate and mercuric chloride between the light source and the mirror in the Duboscq colorimeter. Fig. 292 shows the assembled apparatus, including the shield used to eliminate stray light rays, the colorimeter lamp and filter, the Duboscq colorimeter and the removable shield for the latter. There was found to be a rough correlation between the optical density color and the National Petroleum Association color.[91]

The color of petroleum distillates other than lubricating oils is also of some importance.[92] For example, Rabinovich and Abakova[93] have investigated the color of paraffin wax by comparison of the wax with standard solutions of variable depth.

INORGANIC CONSTITUENTS

The determination of the inorganic constituents of petroleum distillates is not usually necessary in the analysis of lubricating oils,[94] particularly if the latter be completely miscible with naphtha or benzene.[95] The usual procedure is to burn a weighed sample and ignite the residue. The residue is weighed and the ash content calculated from this value.

Schmeling[96] has suggested that, prior to the ignition of a wet oil, the moisture be partially removed by absorption with a filter paper moistened with alcohol. Alcohol is then added to form a layer and the paper used as a taper. Finally, the oil is ignited and the ash weighed. The percentage of alkali metals (sodium and potassium) present in lubricating greases may be ascertained in the following manner. The ash from burning the sample is extracted with hot water and this extract added to oleic acid in ethanol until the solution is alkaline. The alcohol is removed by evaporation, 5 volumes of distilled water are added, and any insoluble calcium soaps filtered off. Alkali metal soaps make this filtrate froth readily and give a precipitate with barium chloride. The alkali metals may be determined quantitatively by converting them to the sulphates, precipitating with barium hydroxide, filtering, and precipitating calcium, strontium and barium with ammonium carbonate. Excess of the latter reagent is destroyed by boiling, and the alkali metals are determined by titration with acid.[97]

It is sometimes necessary to determine the amount of lead present in greases where it may be present as soaps. Bauer and Ford[98] recommend that 10 g. of the oil be ignited and allowed to burn to dryness in a porcelain crucible. The residue is then heated with sulphuric acid until fuming commences, a few drops of nitric acid are added and heating continued. This is repeated until the residue is white. The lead sulphate is then dissolved in ammonium acetate solution, a small amount of acetic acid being used to dissolve any lead hydroxide that is formed. The solution is filtered, the residue washed with acetic acid and finally with hot water until free from lead. Lead is precipitated from the filtrate by the addition of sulphuric acid. The lead sulphate is filtered onto a Gooch crucible, washed with dilute sulphuric acid, ignited and weighed. Another procedure has been suggested by Levin.[99] This consists essentially in extracting the lead from the oil by heating the latter with a mixture of glacial acetic acid and benzene. Lead is precipitated from the extract by potassium chromate.

Because of the use of tetraethyl lead as an antiknock agent (Chapter 44), it is sometimes necessary to determine its concentration in gasoline. The quantitative methods usually are based upon the decomposition of the lead alkyl by different agents, for example, sulphuric acid,[100] bromine,[101] hydrochloric acid,[102] nitric acid,[103] iodine and sulphur monochloride.[104] In this manner lead is obtained in the form of inorganic salts which in most cases are converted into the sulphate or chromate for gravimetric determination. The use of the spectroscope[105] and of x-rays[106] has also been suggested as agents for the determination of lead in gasoline. The method of Baldeschwieler[107] is said to be somewhat more simple than many others. This depends upon decomposition of the tetraethyl lead by concentrated nitric acid. The procedure is to shake 200 cc. of gasoline with 20 cc. of concentrated nitric acid in a 500 cc. glass-stoppered separatory funnel for 15 minutes. The layers are separated after 2 minutes standing, and 20 cc. of water shaken with the gasoline layer for 15 minutes. The water layer is separated and the washing repeated. The aqueous layers are combined and evaporated to a volume of 20 cc. The solution is cooled and 15 cc. of concentrated sulphuric acid added. This is boiled until fumes of sulphur trioxide appear. Any organic matter is destroyed by the careful addition of nitric acid. After there is no more organic matter present, and the solution has become colorless, the latter is cooled and diluted with 20 to 25 cc. of water and again evaporated to the appearance of sulphur trioxide fumes. It is cooled again and diluted to 150 cc., then cooled in an ice-bath for 1 hour and filtered through a previously ignited and weighed Gooch crucible. The residue (lead sulphate) is washed with 2 per cent sulphuric acid, then with ethanol, dried, ignited and weighed. The grams of lead sulphate per cc. of sample may be multiplied by 2445 to give the number of cc. of tetraethyl lead per gallon of gasoline. The total time for the analysis is said to be about 4 hours.

DETERMINATION OF ACIDITY AND SAPONIFICATION NUMBER

Acid bodies in petroleum products are considered particularly undesirable because of their tendency to corrode the metal parts of machines or containers with which they come in contact. For example, lubricating oil in which acids are present, whether as petroleum acids or sulphuric or sulphonic acids, may effect corrosion of the metal bearings of automobiles.

Acidity may be expressed as the neutralization number, that is, the weight in milligrams of potassium hydroxide required to neutralize one gram of the oil.[108] A sample of the oil is shaken with neutral ethanol and the hot extract titrated with potassium hydroxide using phenolphthalein as an indicator.[109] It is suggested that the mineral acid neutralization number be estimated by extracting the oil several times with hot water and titrating these extracts, employing methyl orange as an indicator. In some instances the aqueous liquid is alkaline, in which case phenolphthalein is substituted for methyl orange, and the alkali neutralization value (milligrams of potassium hydroxide equivalent to the acid used per gram of sample) is ascertained.

Ruibak[110] recommends a somewhat different procedure for inorganic acidity. He uses a reference solution of sodium naphthenates in alcohol of which 20 cc. are added to a 50 g. sample of oil. The alcohol layer is separated after shaking and 5 cc. portions are titrated with 0.1*N* hydrochloric acid. From the known titer of the reference solution it is then possible to calculate the inorganic acidity of the oil as:

$$\text{Per cent sulphuric acid} = a - (20/C)b\,K \times 0.0049 \times 8$$

where *K* is the normality of the hydrochloric acid, *a* is the titer of the sodium naphthenate solution (cc. of standard acid required to neutralize 5 cc.), *b* is the volume of standard acid to neutralize the extract and *C* is the volume of extract.

The presence of acids in oils has been determined also by potentiometric titrations. This has advantages in both accuracy and applicability to opaque liquids. For example, Vellinger[111] has described the use of an antimony electrode for the titration of acid in mineral oil. He suggested the use of a solution of the sample in diethyl ether, ethanol or pentanol. Pavlovskiĭ[112] has outlined a potentiometric method using platinum-hydrogen electrodes. One is placed in a neutral medium, the other in the sample. At zero potential difference, when titrating with alkali, neutralization is complete. Evans and Davenport[113] employ a glass electrode and a silver-silver chloride reference electrode with transformer oils. The arrangement was:

Ag, AgCl	Saturated KCl in butanol	Sample in butanol	Glass	.003M Picric acid in butanol	Quinhydrone, Platinum

The butanol was rigorously purified by distillations from potassium hydroxide. α-naphthol, *m*-phenylenediamine hydrochloride and freshly heated lime. Volatile acids were then removed by purging with purified nitrogen for 30 minutes. It was found necessary to have at least 1 per cent of water in the butanol to obtain satisfactory results. A vacuum-tube potentiometer using a galvanometer with sensitivity 4×10^{-10} amperes as null point detector permitted an accuracy of 1 per cent of measured voltage with a current of less than 10^{-15} amperes. The results were plotted as rate of change of voltage per 0.10 cc. of added solution against the volume of added solution. This gave a very sharp maximum at the end point, which could be determined by extrapolation of the curves before and after this point. It was found that the presence of substances such as metallic soaps and peroxides interfered with the accuracy of the results. In the absence of any interfering substances, the accuracy was ±0.001 on the neutralization number as determined on a 20 g. sample.

Saponification number is expressed as the number of milligrams of potassium hydroxide required to react with the esters in 1 g. of oil. The value is usually fairly low for petroleum products. It is determined by saponifying a weighed sample with 25 cc. of standard alkali in the presence of 25 cc. of neutral ethanol. The excess alkali over that required in saponification is determined by titration with $0.5N$ hydrochloric acid.[114]

WATER CONTENT OF PETROLEUM FRACTIONS

The presence of water in lubricating oils or motor fuels is considered undesirable because it tends to separate when the latter are cooled. In an aviation gasoline, for example, this may lead to clogging of the fuel lines and consequent endangerment of life. Some procedures involve separation of water by physical means, e.g., by distillation or centrifugation. Others are based on the reaction of this liquid with some reagent and measurement of the products formed, for example, the liberation of hydrogen by interaction with calcium hydride (see below).

The procedure, recommended by the A.S.T.M.,[115] is that of placing 100 cc. of the oil to be tested in a 500 cc. flask together with an equal volume of water-free gasoline and then distilling the latter. The vapors pass through a delivery tube to which is fused a graduated trap and into a condenser placed above the trap. The condensate flows over the trap, in which water is collected, and the gasoline returns to the flask. Distillation is continued until no more water separates. The volume of water (in cc.) is read from the graduations on the trap. A modification consists in distilling the sample with xylene or toluene and dehydration of the distillate with a weighed amount of anhydrous copper sulphate. The percentage of water can then be calculated from the increase in weight of the copper sulphate. This method is said to be quite flexible in its applicability.[116]

[115] A.S.T.M. Designation D 95-30; A.S.A. No. Z11. 9-1930; A.P.I. No. 519-30; "A.S.T.M. Standards," American Society for Testing Materials, Philadelphia, Pa., 1933.

Another procedure comprises centrifuging the specimen and measuring the volume of water and sediment which separates. This is not entirely satisfactory because the amount of water found is usually lower than the actual amount in the sample.[117]

The determination of water in gasoline by chemical means has been suggested. Thus, Dietrich and Conrad[118] report that it is possible to react the water quantitatively with magnesium nitride. Ammonia is formed by this reaction and is determined by distillation of a portion of the sample into a measured volume of standard acid, followed by titration of the excess acid. This method is said to be applicable even in the presence of alcohols, although some methylamine apparently is formed if there is more than 60 per cent of methanol in the sample. The applicability of the method to the determination of water in petroleum products, as well as many other liquids, has been studied by Boisselet and Rachkani.[119] They found that the procedure is quick and easy, the limiting factor for accuracy being the purity of the magnesium nitride.

By treating the wet sample with substances which will liberate gases, such as hydrogen, the water content may be estimated gasometrically. Thus, Broche and Scheer[120] treated 100 cc. of oil with about 1 g. of calcium hydride and measured the evolved gas. Similarly, Cords[121] has determined the amount of water in a gasoline by measurement of the volume of gas produced by the action of sodium on a liter of the gasoline. This test requires about 48 hours for completion, and is consequently somewhat more time-consuming than the use of calcium hydride.

ANALYSES OF PETROLEUM DISTILLATES BASED ON PHYSICAL CHARACTERISTICS

In addition to the various methods for the analysis of petroleum fractions which depend on the chemical reactivity of one or the other hydrocarbon groups present in various cuts, a number of physical properties or characteristics of the different fractions have been adapted to the estimation of the nature of the distillate.[122]

One of the most common of these physical properties is the vapor pressure, which is measured rather indirectly by distillation tests, either at atmospheric or reduced pressures. Specific gravity is determined for petroleum fractions not necessarily as a characterization factor by itself but because it is of use in conjunction with other characteristics.[122a]

Other properties which are occasionally used are specific refraction, surface

tension, parachor,[123] and critical solution temperatures. Chilling tests (cloud and pour point) and molecular weight determinations are often carried out on petroleum fractions. The determination of Raman spectra for petroleum distillates has been suggested, although but little used.

Distillation and Vapor Pressure Tests. The analytical procedures which are dependent upon changes in vapor pressure may be classed as (a) evaporation tests; (b) vapor pressure measurement; and (c) distillation tests.

The rate of evaporation of a solvent is well known to be of importance in connection with the properties of paints and other protective coatings. Too high a rate results in cooling during drying and condensation of moisture on the surface of the coating. This may result in "blushing." In motor fuels, too rapid evaporation or too great volatility may result in vapor lock.[124] (See Chapter 44.)

The measurement of vapor pressure has been effected in several ways. The A.S.T.M. method[125] depends upon volatilization of the gasoline being tested in a cylinder equipped with a pressure gauge. The determination may be carried out at temperatures from 32° to 110°F. and corrected to give the value at 100°F. (Reid vapor pressure) by means of tables.[126] Lederer has shown that vapor pressure, p, at temperature, T, may be calculated from the equation:

$$\log\frac{pS}{p} = (q/4.571)\,(T^{-1} - TS^{-1})$$

where T_S is boiling point at atmospheric pressure, p_S, and q is molar heat of vaporization.[127] By consideration of his experimental results, he concluded that there was some relationship between vapor pressure and both viscosity and flash-point.

Distillation has long been used to indicate the degree of purity of organic compounds. The distillation of various of the lighter petroleum fractions is regularly undertaken as an indication of their nature.[128] By plotting the volume of distillate against the temperature of distillation and connecting the points, curves are obtained which are spoken of as "distillation curves." The various points on this curve have been used as indications of the nature of the fuel in practice. The 10 per cent point, for example, is considered to be an indication of the ease of starting.[129] The quick warming-up characteristics are indicated by the 35 per cent point and steady driving by the 60 per cent point. It is also possible to determine the content of butanes, pentanes, hexanes, and higher homologues from the Engler (A.S.T.M.) distillation curve of a gasoline. This is accomplished by reference to empirically determined graphical relationships.

For substances which are relatively volatile, such as gasoline and kerosene, it is possible to conduct distillations under atmospheric pressure. On the other hand, the low volatility of heavy stocks e.g., lubricating oils, precludes their distillation except under rather high vacuum.[130] Schicktanz[131] suggested an apparatus for the accurate determination of boiling points of lubricating oils and other high boiling substances. Three thermocouples are placed at different heights in the fractionating column. For a pure substance their readings should be the same, and the difference between their readings is a qualitative indication of the purity of the substance. Watson and Wirth[132] have outlined a procedure for the distillation of oils under a pressure of about 0.1 mm. of mercury. The sample (200 cc.) is first distilled under atmospheric pressure up to 500°F. A portion of the bottoms from this distillation equivalent to 100 cc. of the original oil is then distilled under reduced pressure. From the boiling range data for the latter distillation, it is possible to obtain the boiling range at normal pressure by the use of a nomogram.[133]

Steam-distillation at constant temperature has been proposed as a method for determining the volatility range of high-boiling petroleum fractions. The operation is carried out at a temperature between 320 and 350°C., and the proportion of oil in the distillate is ascertained at regular temperature intervals. Plotting temperature against volume of distillate gives a step-like curve. By connecting the mid-points of the horizontal portions of the curve, a line is obtained which represents fairly closely the volatility curve for the oil.[134]

Flash Point. The flash point of an oil may be defined as the temperature at which an oil evaporates so intensively that its vapor, in an open space of specified dimensions or in a specified container, forms an ignitable mixture with air. The flash point is of value in indicating the fire hazard resulting from the storage or employment of the oil. The "burning point" is also of importance in this connection. The latter is the temperature at which the vapors not only flash but continue to burn.[135] The lower these two temperatures, the greater the danger of the oil volatilizing sufficiently to form an explosive mixture with the surrounding air.

The methods by which flash-point may be determined specify the conditions under which the test is to be performed quite closely because of the influence of the dimensions of the space in which the flash occurs upon the flash-point. One form of apparatus is the Cleveland Open Cup which has been adopted by the A.S.T.M.[136] The oil to be tested is heated in a standard cup at a rate of about 10°F. per minute as the temperature approaches the probable flash-point. When the temperature of the oil passes every 5°F. mark on the thermometer immersed in it, a test flame of specified dimensions is applied to the sample. The results obtained by this test may be evaluated only in terms of other tests.[137] The other forms of apparatus consist essentially of a closed cup. Examples of this type are the Abel Tester, the Tag Closed Tester and the Pensky-Martens Closed Tester. The latter two are standard in the United States for volatile flammable liquids (boiling below 175°F.) and fuel oils, respectively. The Abel Tester was specified for use in the examination of petroleum products by The Petroleum Act of 1879.[138] In general, it is very similar to both the Pensky-Martens and Tag closed testers, in which the oil sample is heated and its vapors intermittently exposed to a flame of certain dimensions.[139]

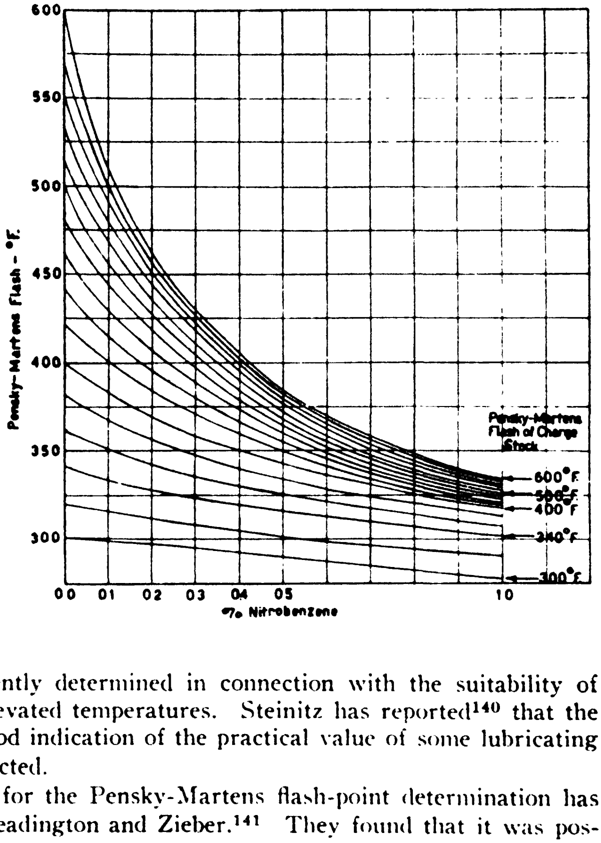

FIG. 293.
Chart for Determination of Nitrobenzene Content of Mixtures with Hydrocarbon Oils by Measurement of Flash Points. (S. S. Kurtz, Jr., C. E. Headington and B. Zieber)

Courtesy Industrial and Engineering Chemistry

The flash-point is frequently determined in connection with the suitability of lubricating oils for use at elevated temperatures. Steinitz has reported[140] that the flash-point did not give a good indication of the practical value of some lubricating oils in tests which he conducted.

A rather interesting use for the Pensky-Martens flash-point determination has been suggested by Kurtz, Headington and Zieber.[141] They found that it was possible to determine the amount of nitrobenzene present in the raffinate from the solvent-refining of lubricating oils using nitrobenzene. This method is applicable only to oils flashing between 300 and 600°F. (149° and 316°C.) which contain 1 per cent or less of nitrobenzene. The procedure involves ascertaining the flash-point of the oil before treatment and then of the raffinate containing nitrobenzene. By means of the curves shown in Fig. 293 the per cent of nitrobenzene may be read off. For example, if the original flash-point was 440°F. and the flash-point of the sample containing nitrobenzene was 330°F., by reference to the chart it is found that there is 0.83 per cent of nitrobenzene in the sample.

---

[138] This method is summarized, together with the other early procedures, in A. H. Allen, "Commercial Organic Analysis," 3rd Ed., revised by H. Leffmann, P. Blakiston's Son & Co., Philadelphia, Pa., 1900.

Determination of Molecular Weight. There are three common procedures for the estimation of molecular weight, viz., the vapor pressure, cryoscopic and ebullioscopic methods. These are characterized by rather limited applicability. The vapor pressure method of Victor Meyer is rather difficult to apply to substances of high boiling point, although Nernst[142] has designed an apparatus of pure iridium which he used up to more than 2000°C. The method is to weigh out a small amount of the sample, which is then introduced into a vessel where it can be heated so that it is completely vaporized. By measurement of the increase in volume, the temperature and pressure and application of the ideal gas laws, it is then quite simple to calculate the molecular weight of the unknown. This method has been recommended by Newman and Meanes.[143]

Cryoscopic methods have the disadvantage that many substances tend to crystallize out of the solvent medium on cooling. On the other hand, there is less likelihood of loss of the sample through volatilization. A number of compounds have been recommended as the liquid media in the determination of molecular weights by this procedure. Camphor is quite satisfactory in many instances,[144] although benzene is widely employed[145] as is also nitrobenzene. In some cases where peculiarities of the material under investigation make the above solvents unsatisfactory, dioxane and ethylene dibromide have been used.[146] Fenske, McCluer and Cannon[147] suggested cyclohexane as a solvent and found that values secured with this liquid checked fairly satisfactorily with results obtained by computations from molal heats of vaporization.

The ebullioscopic method for molecular weight determination has the disadvantage of loss of sample by volatility. Mair[148] has observed that extrapolation of the results to infinite dilution for purposes of calculation gives values that agree with theory rather well. This was done by determination of several values for the boiling point elevation using different concentrations of the solute, and plotting these against concentration. Extrapolation was then very easily effected.

Viscosity. The determination of viscosity has long been one of the standard procedures in the control of petroleum products, particularly the higher boiling fractions which are used as lubricants.[149] The most common methods for the measurement of viscosity depend upon the relationship established by Poiseuille[149a]:

$$V = \frac{\pi g p R^4 t}{8 l \eta}$$

where V is the volume of oil of viscosity, η, which passes through a capillary tube of radius, R, and length, l, in time, t, under pressure, p, when g is the acceleration due to gravity.[150] The instrument to be used is so constructed and the conditions of the experimental determination so fixed that:

$$\eta = (C)t$$

where C includes all the other terms of the equation. Some of the methods which involve this generalization are the Engler, Saybolt, Redwood, Barbey, Lamansky-Nobel[151] and many others.[152] The general procedure is to time the flow of oil through a capillary of standard dimensions until a given volume of oil has been collected in a calibrated flask. In the Saybolt Universal and Furol Viscosimeters, also known as viscometers, this volume is 60 cc.,[153] though in the Engler viscometer it may be 50, 100 or 200 cc. depending upon the viscosity of the oil.[154]

Viscosity is of two kinds, namely, dynamic, which is expressed in poises, and kinematic,[155] which is expressed in stokes. The relationship, where P is dynamic and K kinematic viscosity and d the density of the substance, is

$$P = K/d$$

Relationships between these absolute units and the arbitrary units such as Saybolt seconds, Engler degrees and Redwood seconds have been established by various workers.[156] The relationships vary somewhat in different ranges of viscosity.

[149] Although most physical properties of mixtures are additive and follow the rule of mixtures, A. N. Hartmann (*3rd Collection of Articles of the Inst. of Materials of People's Commissariat of Communication (Moscow)*, 1929, Issue **8**/112, 40; *Chem. Abs.*, 1930, **24**, 5472) has observed that this was not true of the viscosities of creosote-fuel oil mixtures. For a method of plotting viscosity gravity constants against volume per cent of solvent in an extract to obtain regions of complete and partial miscibility, see S. S. Kurtz, Jr., *Ind. Eng. Chem.*, 1935, **27**, 845; *Chem. Abs.*, 1935, **29**, 5311; *Brit. Chem. Abs.* **B**, 1935, 753.

[154] D. Holde and E. Mueller, "The Examination of Hydrocarbon Oils," John Wiley & Sons, Inc., New York, **1915**. According to F. H. Garner and W. E. J. Broom (*Rev. pétrolifère*, 1935, No. **647**, 1204; *J. Inst. Pet. Tech.*, 1936, **22**, 27; *Chem. Abs.*, 1936, **30**, 1624; *Oel, Kohle, Erdoel, Teer*, 1936, **12**, 77) the Engler instruments are less accurate than either the Redwood or Saybolt.

[155] G. Barr (*Proc. World Petr. Congr.*, 1933, **2**, 508; *J. Inst. Pet. Tech.*, 1934, **20**, 296A; *Chem. Abs.*, 1934, **28**, 4887; *Brit. Chem. Abs.* **B**, 1934, 656) has suggested the word "lentor" as a name for kinematic viscosity. Dynamic or absolute viscosity is the expression of the internal friction of fluids in absolute units. The unit employed is the poise, or force in dynes per sq. cm. required to move a surface of 1 sq. cm. at a velocity of 1 cm. per sec. past an equal surface 1 cm. distant, when the space between surfaces is filled with the fluid under investigation. Kinematic viscosity is the quotient, in stokes, of the dynamic viscosity divided by the density of the fluid. See V. A. Kalichevsky and B. A. Stagner, "Chemical Refining of Petroleum," The Chemical Catalog Co., Inc., New York, **1933**. W. H. Walker, W. K. Lewis, and W. H. McAdams, "Principles of Chemical Engineering," McGraw-Hill Book Co., Inc., New York and London, **1923**. A. W. Nash and A. R. Bowen, "The Principles and Practice of Lubrication," Chapman & Hall, Ltd., London, **1929**.

[156] See, for example, F. H. Garner and C. I. Kelly, *Physics*, 1933, **4**, 97; *Petroleum Z.*, 1933, **29** (28), 1; *Chem. Abs.*, 1934, **28**, 621; *Brit. Chem. Abs.* **B**, 1933, 767. Chem.*, 1935, **27**, 82; *Brit. Chem. Abs.* **B**, 1935, 613; *J. Inst. Pet. Tech.*, 1935, **21**, 87A; *Chem. Abs.*, 1935, **29**, 1971. F. H. Garner, W. E. J. Broom and J. L. Taylor, *J. Inst. Pet. Tech.*, 1936, **22**, 11; *Chem. Abs.*, 1936, **30**, 2818. L. Ubbelohde, *Chem.-Ztg.*, 1907, **31**, 38; *Chem. Abs.*, 1907, 1, 1087. *Cf.* I. D. Afanasyev, *Neft. Khoz.*, 1929, **17**, 218; *Brit. Chem. Abs.* **B**, 1930, 402; *Chem. Abs.*, 1930, **24**, 952.

The various arbitrary units are also interchangeable by the application of suitable equations.

An instrument which is also based on the rate of flow of an oil through a capillary tube is the Ostwald viscometer. Willihnganz and his co-workers[157] have described a modification of this instrument which is said to be more satisfactory than the usual type. An Ostwald viscometer which can be used for the measurement of the viscosity of tar has been suggested by Lee.[158] Ubbelohde[159] has described a "suspended-level" viscometer which is reported to be an improvement over the usual instruments in several ways, such as the replacement of the lower liquid level by a suspended level.

A modified form of the Ubbelohde suspended-level viscometer has been designed by FitzSimons.[160] This instrument is said to surpass the more ordinary types of viscometer in speed, accuracy, and in ease of operation. The apparatus is shown in Fig. 294. The description of the apparatus and procedure is:

> The apparatus consists of two capillaries of different sizes, A, sealed into a vapor bath, E. "Tube C is an air vent for producing the suspended level and tube B is connected to the oil reservoir, D.
>
> "The bulb is filled with a pure organic liquid with a normal boiling point slightly above the temperature at which it is desired to operate the viscometer, methylene chloride being suitable for use at 37.78°C. (100°F.) and tertiary amyl alcohol for use at 98.89°C. (210°F.). Vacuum is turned on and regulated by Valve I to obtain a slow rise of bubbles up Column J. The bulb, H, is heated electrically causing vapor to rise up the jacket and down the riser, F, to the condenser, G, and return as liquid to the bulb, H. To obtain exactly the desired temperature, the pressure is adjusted by adding or removing water from the pressure-regulating column, J, by means of the leveling bottle, K. By changing the connection to the column from Tube L to Tube M and substituting an air line for the vacuum line, the viscometer can be operated under pressure; this is occasionally necessary on days of low barometer.
>
> "Oil is poured through a 100-mesh filter down Tube B until reservoir D is about one-half full; this requires about 12 cc. After a short wait of 1 to 2 minutes to allow the oil to reach bath temperature, Tube C and the smaller capillary, A, are closed off with the fingers and oil is drawn up into the right capillary by suction well above the upper mark. The suction line and fingers are then removed, establishing the suspended level at N, and the time for the oil to pass between the marks is noted. If the time is less than 100 seconds the oil is immediately drawn up into the smaller (left) tube and the efflux time observed. The kinematic viscosity is obtained by multiplying the efflux time by a factor determined by calibrating each tube of the instrument on an oil of known viscosity. At short efflux times a kinetic energy correction is necessary, which is always less than 1 per cent for motor oils. The kinetic energy correction is calculated from the dimensions of the instrument.
>
> "The oil is quickly removed through Tube C by a suction line connected to a trap. The instrument is flushed with a narrow cut naphtha with an initial slightly above the bath temperature. The naphtha is also removed by suction through Tube C and the instrument sucked dry. The entire cleaning operation requires about one minute."

Other methods which have been used for the determination of viscosity include the falling sphere[161] and its modification in which a bubble is permitted to rise through the liquid.[162] Another variation consists of permitting spheres of known dimensions to fall through a column of the oil which is somewhat inclined.[163] A method which is analogous to the falling sphere method is that described by Duffing.[164] In his method, using what he calls a viscometric balance, a sphere rises a known distance through a liquid under the influence of a force applied by means of a weight on the other arm of the balance. The results from this apparatus are calculated directly in centipoises. Yet another viscometer is that which has been advocated by Smith[165] and employed by him in studying the effect of carbon suspensions on the properties of lubricating oils. The method consists essentially in counting by means of a photo-electric cell the number of drops falling from an orifice.

The Expression of the Temperature Variation of Viscosity. In the previous discussion of viscosity it has been pointed out that viscosity is commonly expressed in either absolute units, such as poises or stokes, or in arbitrary units such as the Saybolt second or Engler degrees. These measurements give an indication of the viscosity only at the specified temperature at which they were determined. Numerous methods have been suggested by which it would be possible to indicate by means of one value the extent to which viscosity changes at rising temperatures. One of these methods was the ratio of the viscosities at 100 and 210°F. The Viscosity Index was first suggested by Dean and Davis[166] as a method for evaluating the variation of viscosity with temperature and was later discussed by Davis, Lapeyrouse and Dean and others.[167] To determine the viscosity index (V.I.) of an oil it is compared with two other oils whose viscosities at 210°F. are the same as the unknown. The two standard oils are chosen from such a stock that they differ widely in viscosity at 100°F. If the unknown has a viscosity V at 100°F., and the standards, viscosities of L and H at 100°F. for oils of poor and good (Gulf Coast and Pennsylvania base) qualities, respectively, the viscosity index is then given by the equation,

$$\text{V.I.} = \frac{L - V}{L - H} \times 100$$

Thus, an oil which compares favorably with oils of Pennsylvania origin and has relatively low change of viscosity with temperature will have a V.I. near 100, and an oil with wide variation in viscosity with temperature will have a V.I. near zero.

Other methods have been suggested for representation of change of viscosity such as the Viscosity Gravity constant of Hill and Coats,[168] the Gravity-Index[169] and numerous other systems.[170]

Tests for Cloud and Pour Points. The cloud point of a petroleum oil is defined as "the temperature at which paraffin wax or other substances begin to crystallize or separate from solution when the oil is chilled under definite prescribed conditions."[171] "The pour point of a petroleum oil is the lowest temperature at which the oil will pour or flow when it is chilled without disturbance under definite prescribed conditions." It has been observed that cloudiness may be due to water, soaps, sodium sulphate or ceresin.[172] The pour point and cloud point depend to some extent upon the treatment which the oil has undergone. Heating the oil, even only above 100°F., makes it necessary to wait some time before testing. There is some tendency for asphaltenes to keep wax in solution in this determination, particularly if there is any pronounced agitation during cooling.

Use of Specific Refraction and Specific Dispersion in Examination of Petroleum Fractions. Specific dispersion is defined as 10,000 times the difference between two specific refractions. That is, for refractive indexes for the C and G′ lines,[173] the specific dispersion, *D*, may be written:

$$D = \left(\frac{n_{G'} - 1}{d} - \frac{n_C - 1}{d}\right)10^4$$

where $n_{G'}$ and n_C are refractive indexes for G′ and C lines, respectively, and d is the specific gravity. By using molar refractives, as given by the Lorentz-Lorenz formula,[174] in place of the specific refractions used above, the specific dispersion is given by the equation:

$$D = \left(\frac{n_{G'}^2 - 1}{n_{G'}^2 + 2} \cdot \frac{1}{d} - \frac{n_C^2 - 1}{n_C^2 + 2} \cdot \frac{1}{d}\right)10^4$$

The advantage of this formula is that it is possible to calculate n by the use of atomic refractions. The values obtained in this way are usually fairly satisfactory for saturated compounds but not for aromatic or unsaturated hydrocarbons.[175] The first equation above may be written

$$D = (n_{G'} - n_C)10^4/d$$

By substituting experimentally determined values for n_C and $n_G{}'$ it is possible to obtain values of *D*. After treatment of a specimen to remove aromatic compounds *D* should be less than 158.[176]

Marder[177] has outlined a procedure for estimation of the relative amount of paraffin and naphthene hydrocarbons in an oil from which olefins and aromatics have been removed by sulphuric acid treatment. This method depends upon a knowledge of the specific refraction of the sample being tested and of paraffins and naphthenes which are known to lie within the boiling range of the specimen.

Vlugter, Waterman and van Westen[178] have shown that the composition of a

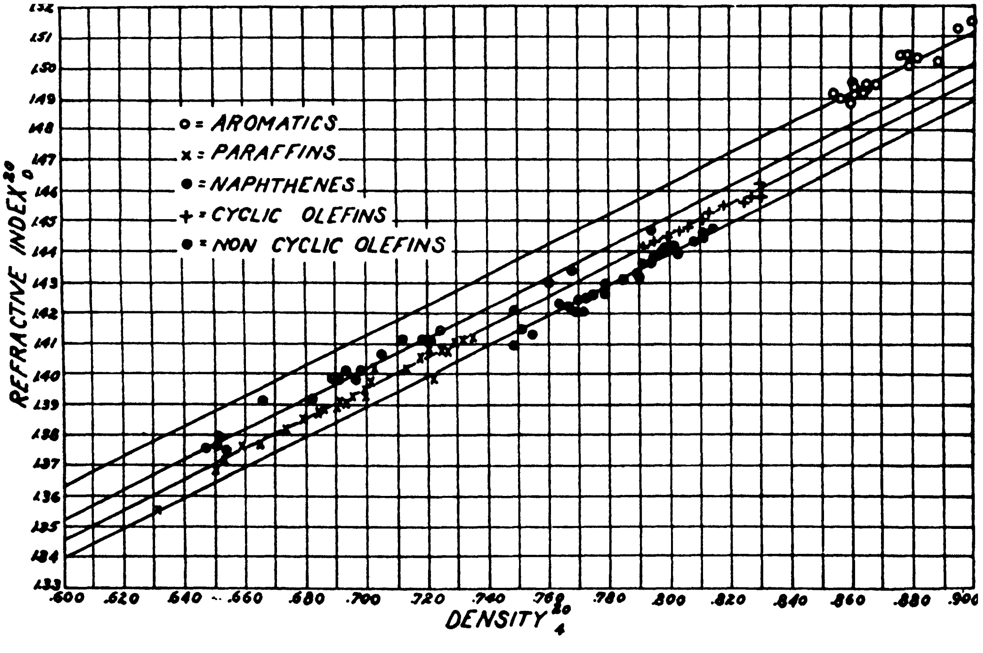
high-boiling mixture of hydrocarbons may be most satisfactorily expressed as per cent each of aromatic rings, naphthenic rings and paraffin-side-chains. They showed that the composition could be calculated from a knowledge of the molecular weight, refractive index, density and aniline point of the oil. This was made possible in part by means of experimentally determined graphs and partly by calculations involving the known values.

A method for determining the various homologous series of light petroleum fractions has been advanced.[179] It depends upon the fact that for a given structural type of hydrocarbon, the refractive index varies linearly with the density. When these data are plotted, the equation which describes the relation is shown to be



Courtesy Industrial and Engineering Chemistry

FIG. 295.—Derivation of Refractivity Intercept for Hydrocarbons. (S. S. Kurtz, Jr., and C. E. Headington)

$$\text{Refractivity index} = 0.5 \text{ density} + b$$

where b is a constant which represents the refractive index at zero density. This value, called the refractivity intercept, is different for each homologous series, as may be seen from Fig. 295. Some of the refractivity intercepts are indicated in Table 213.

Examination of Petroleum Fractions by Means of Critical Solution Temperatures. The temperature at which an oil and a solvent liquid become completely miscible is known as the "critical solution temperature." Because of the different solubility of the several classes of hydrocarbons in solvents, such as

Noncyclic nonconjugated diolefins	1.0592

aniline, nitrobenzene or benzyl alcohol, it is possible to obtain an indication of the nature of an oil from its critical solution temperature in one of those solvents.[180] In determining the amount of naphthenes and paraffins in an oil after hydrogenation of aromatics and olefins, Vlugter, Waterman and van Westen[181] have used the aniline point as a means of indicating complete hydrogenation. According to Griffith and Hollings[182] the portion of oil which is insoluble in oleum is also least soluble in aniline. They also suggested that curves of aniline point versus boiling point gave some indication of the previous history of the oil. An oil which had undergone cracking treatment gave a flexed curve, whereas with a crude oil the graphic relation was linear.

Besides aniline, nitrobenzene and benzyl alcohol, several other organic liquids have been used in the study of critical solution temperature. A solution of 9 parts acetone and 1 part amyl acetate is recommended by Vellinger and Herrenschmidt[183] for highly refined oils. Nitromethane has been proposed as a medium for the identification of the types of hydrocarbons.[184] Thus, solid aromatic hydrocarbons are more soluble than other hydrocarbons of approximately the same melting point and molecular weight. In approximately increasing order of solubility in nitromethane at 20°C., the various hydrocarbons are: alkanes, cycloalkanes, dicycloalkanes, cycloalkenes, alkadienes containing more than eight carbon atoms, alkynes, alkenes and aromatics. The latter are much more soluble than any other type. The critical solution temperatures of various hydrocarbons in liquid sulphur dioxide and likewise in liquid ammonia have been determined as a possible means for the separation of isomers.[185] However, it appears that aniline holds more promise than either of the last-mentioned solvents.

The kauri-butanol test for solvent power may be considered as dependent upon critical solubility. It consists of ascertaining the volume (in cc.) of a solvent which will cause sufficient opacity, when added to 20 g. of standard kauri solution at 77°F., to make 10 point print illegible when viewed through the flask.[186] "The standard kauri solution is prepared by adding 100 g. of carefully selected kauri gum to 500 g. of *n*-butyl alcohol (distilling between 114.4 and 116.6°C.). The mixture is heated gently in a flask provided with a water-cooled reflux condenser, allowed to cool, and after 96 hours decanted into a clean, dry bottle always kept well stoppered." Higher-boiling butanol may be used. The test is carried out in a 250 cc. flat-bottomed flask, the solvent to be tested being run into the kauri-butanol solution in the flask until the end point is reached. Because of the variation in kauri gum from different sources, it is necessary to correct the kauri-butanol values to some standard. Benzene is used for this purpose, its kauri-butanol value being determined and known as the "benzene equivalent" of the kauri solution. To make final results comparable, the kauri-butanol value as determined is divided by the benzene equivalent of the solution and multiplied by 100. The kauri-butanol value is considered to be an indication of aromaticity of a solvent. It is recommended as an index of solvent power for hydrogenated petroleum solvents by Baldeschwieler and his co-workers. Aniline point has also been recommended as an index of solvent power in petroleum solvents to be used in paint formulation.[187]

Surface Tension and Parachor in the Analysis of Petroleum Fractions. Surface tension may be defined as the force at the surface between two fluids which is due to molecular attractions. Air is commonly taken as one phase. The surface tension, γ, may be measured by a rise, h, in a capillary radius, r, for a liquid of density, d, according to the formula:

$$\gamma = rhdg/2$$

The tension will be found in dynes per centimeter, if r and h are in cm., d in grams per cm.^{3} and g (the acceleration due to gravity) in cm. per sec.^{2}

Pfund and Greenfield[188] have proposed a method which is said to be especially practical for the determination of the surface tension of non-volatile, relatively viscous liquids. It depends upon the observation that if a jet of air is permitted to impinge upon the surface of a liquid, the depth of the depression produced is inversely proportional to the square of the surface tension. The depth of the depression is measured by the aid of a short-focus telescope with micrometer eye-piece. A calibration chart to facilitate the determinations is prepared by the use of substances of known surface tension.

A du Noüy tensimeter[189] has been used by Vellinger and Radulesco[190] to study the change of interfacial tension as measured against buffer solutions during refining of mineral oils. They demonstrated that the interfacial tension was higher for more highly refined oils.

The parachor of a substance is defined by the relationship:

$$P = M\gamma^{\frac{1}{4}}/(D - d)$$

where γ is the surface tension, M, the molecular weight and D and d are the densities of liquid and vapor phases, respectively.[191] The value of P, called the molecular parachor, may be calculated with a fair degree of accuracy from values for the different portions of the molecule such as carbon, hydrogen, nitrogen and the halogens. Some of the characteristic increments for parachor are given in Table 214.

The parachor represents a comparison of molecular volumes for liquids at temperatures at which they have the same surface tension. This constant, P, has been found to be useful in determining various properties of substances. For example, it is related to the octane rating of a gasoline (Chapter

44.) Marder[192] has applied the parachor to the determination of the composition of gasoline. He showed that it was possible to determine the extent of elimination of a certain type of hydrocarbon group, such as the removal of olefins or aromatics by sulphuric acid treatment. With unsaturated compounds it was possible to calculate the average number of double bonds per molecule and with aromatic compounds either the degree of hydrogenation for compounds of the lower members or the number of rings per molecule for compounds of higher boiling point. The average number of carbon atoms in naphthene rings can also be calculated.

RAMAN EFFECT IN PETROLEUM CHEMISTRY

Although the Raman effect did not receive very much attention from petroleum chemists during the first few years after its discovery, it has been suggested as a possible means of throwing light on various factors which are of interest in the study of petroleum fractions.[193]

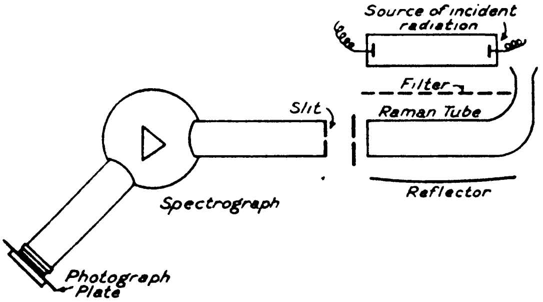

FIG. 296. Diagram of Experimental Arrangement for Recording Raman Spectra. (J. H. Hibben)

Courtesy Industrial and Engineering Chemistry
Courtesy Geophysical Laboratory, Carnegie Institution of Washington, D. C.

In 1928 Raman[194] reported his observations of a new radiation excited in glycerine by ultraviolet radiation. Landsberg and Mandelstam[195] observed the same effect in a quartz crystal at about the same time. This was considered to be the first experimental evidence of a phenomenon predicted earlier by Smekal.[196]

In the determination of the so-called Raman lines, or spectra, it is necessary to use light of a single wave length, as each wave length excites a different group of lines. One of the most satisfactory sources of monochromatic light is the mercury vapor lamp. For several reasons the lines of mercury at 4358 and 4047 Å are used as excitants, in which case it is unnecessary to employ a quartz optical system. A diagram of the apparatus is shown in Fig. 296. It is sometimes found helpful to insert a filter containing mercury vapor between the Raman tube and spectroscope, as this reabsorbs the lines due to the mercury and permits identification of lines close to the exciting frequency.

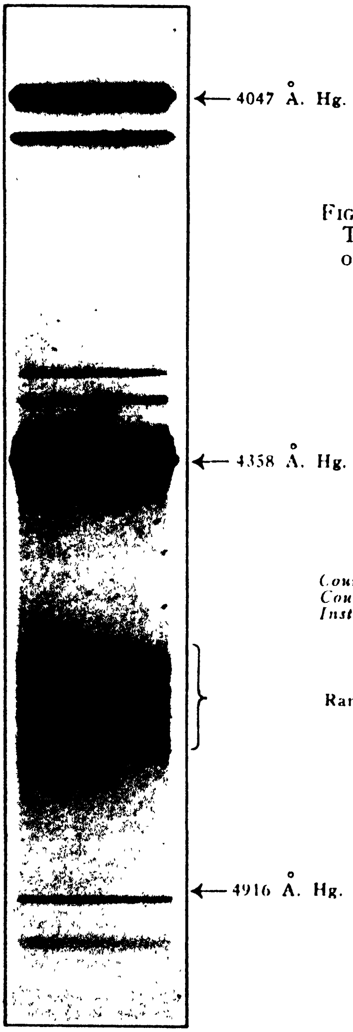

Fig. 297.
Typical Unfiltered Raman Spectrum of Cracked Gasoline. (J. H. Hibben)

Courtesy Industrial and Engineering Chemistry
Courtesy Geophysical Laboratory, Carnegie Institution of Washington, D. C.

The cause of the Raman effect is the loss of energy by quanta of light when they rebound from the molecules of the substance in the Raman tube.[197] Thus, a quantum with the energy hν (where h is Planck's constant and ν is the frequency of the incident light) is absorbed by a molecule and immediately re-emitted with a new frequency ν_1. The energy of the emitted quantum is measured by $h\nu_1$. If energy is given up to the molecule, that is, if $\nu_1 < \nu$, the emitted light will have a longer wave length. The spectral lines which are observed as a result of this are known as Stokes lines. In the opposite case, i.e., if the molecule is in an excited state and gives up energy, the emitted light has a shorter wave length. The spectral lines caused by this are anti-Stokes lines.

---

[197] For a discussion of the mathematics and theoretical aspects of this phenomenon, see G. B. B. M. Sutherland, "Infra-Red and Raman Spectra," Methuen & Co. Ltd., London, 1935.

It has been found that there are certain frequencies of vibration which are more or less characteristic of any particular linkage in a molecule. This frequency is taken up by the molecule when a quantum is absorbed and re-emitted. Consequently the difference $\nu - \nu_1$ is some indication of the nature of the molecule from which the quantum was emitted. It is apparent that this difference should be unaffected by the value of ν, and consequently it is customary to speak of Raman shifts as $\Delta\nu$ expressed in wave numbers per centimeter, i.e., the frequency difference $\nu - \nu_1$.

Although $\Delta\nu$ is more or less characteristic for any particular grouping such as the C-H bond, the nature of the remainder of the molecule has some influence on the frequency of oscillation of the molecule and hence on $\Delta\nu$. A few of the characteristic values for $\Delta\nu$ are shown in Table 215.[198]

TABLE 215.—*Wave Shifts Characteristic of Certain Organic Groupings.*

Bond	($cm.^{-1}$)	Bond	($cm.^{-1}$)
C—H (aliphatic)	2930	C=O	1640 to 1730
C—H (aromatic)	3050	C≡N	2200
C=C	1600	NO_2	1400
C≡C	1960	CH_2	1440

Hibben[199] has suggested that the Raman effect may be of use in study of peroxidation and other phenomena which are of interest in petroleum chemistry. He observed, for example, that aluminum chloride modifies the Raman spectra of a solvent in which it is dissolved. It was believed that this might possibly give some indication of the catalytic effect of aluminum chloride on polymerization. It has also been possible to indicate the nature of the polymerization of compounds such as aldehydes and styrene.[200]

The study of complex mixtures by means of Raman spectroscopy is still rather limited. The presence of as little as 1 per cent of ethylenic substances in cyclopropane has been demonstrated by means of Raman spectra.[201] Although the existence of double bonds in cracked gasoline can be shown more readily by other methods, it is interesting to see that Raman spectra show their presence. In Fig. 297 is shown the Raman spectrum obtained for cracked gasoline, and in Fig. 298 a microphotometer tracing of the spectogram.[202] Some of the lines which could be associated with certain groups have been indicated on the latter figure.

TESTING OF KEROSENE

Many of the tests which have been mentioned heretofore are applicable to kerosene, such as color, sulphur and distillation tests. Also, there are some which are applicable almost solely to kerosene.[203] One of the most important is the "tendency to smoke test," which depends on the aromatic and naphthene content of the oil. The presence of certain amounts of these compounds is desirable as they give to the kerosene some of its useful illuminating properties.[204] The optimum amount is said to be from 10 to 20 per cent, since higher proportions may cause excessive smoking during burning.

The tendency to smoke is measured as the maximum height of non-smoking flame obtainable on burning the kerosene in an especially designed apparatus.[205] Terry and Field[206] have designed a lamp for smoke point the results in which are stated to be reproducible to within 0.10 inch flame height or better. A porcelain dish on which smoke is to collect is cooled by cracked ice. The lamp consists of a brass fount with approximately 4-ounce capacity, wick tube ¼ in. diameter, wick therefor, a brass screen to permit access of air to the flame, a chimney made of 7 in. of 1-in. tubing and a scale of aluminum mounted at the side of the burner. A flame height of approximately 1, 2 or 3 inches characterizes an inferior, well refined or highly refined kerosene, respectively. The test, which consists of turning up the flame until it just smokes, can be completed in about 20 minutes.

FIG. 298.—Microphotometer Tracing of Raman Spectrum of Cracked Gasoline. (J. H. Hibben)

TESTING OF BLENDED MIXED FUELS

In Chapter 44 it was shown that many blended fuels tend to separate in two phases due to the absorption of water. The analysis of the motor fuel to ascertain the relative amounts of gasoline, alcohol and benzene is necessary as this relationship determines to a considerable extent the separating tendency of the product.

A method for the estimation of alcohol in blends with gasoline fractions is extraction of a known volume of sample with 5 volume per cent water followed by measurement of the volume of water layer. Reference to experimentally determined tables made it possible to estimate the original composition.[207] Lampe has suggested[208] determining the density of the benzine portion after separation from alcohol either by treatment with water or, better, an aqueous solution of calcium chloride. If the value is from 0.87 to 0.88, it indicates that the hydrocarbon layer consists of benzene. If only gasoline is present, its specific gravity can be determined from the composition and density of the original mixture.[209]

Herbrich[210] has outlined a method for determining the critical amount of water which will cause separation at 0°C. The procedure is similar to other methods which depend on critical solution temperature.

In determining the amount of alcohol in blends which contain benzene, it is hardly sufficient to add water alone, as there is some tendency for benzene to retain alcohol and vice versa. By using dilute sulphuric acid, which combines with alcohol, Spausta[211] found that it is possible to get complete separation. It is also said to be feasible to isolate certain hydrocarbons for subsequent study. As a suggested color reaction, the addition of specific dyes, algol red B or lacquer red Ciba B, to an alcohol-blended fuel in which there is benzene is said to give a rose or red solution.[212]

Chapter 51

Petroleum Asphalts

Petroleum asphalts are the thick viscous residues obtained by distillation (or cracking) operations, as well as by oxidizing or sulphurizing high-boiling fractions. The proportion of asphaltic (and resinous) substances found in crude petroleums are generally greater the higher the specific gravity and sulphur content of the oil. The data for some American oils are given by Sommer,[1] in Table 216.

TABLE 216.—*Asphalt Content of Various Crude Oils.*

Crude Oil	Sp. Gr.	% Sulphur	% Hard Asphalt
Texas	0.8955	0.33	0.10
Mexican	0.930	3.27	11.08
Californian	0.944	3.3	14.98
Venezuelan	0.980	7.89	17.0

The components of asphalt are usually considered to be oily materials, resins, asphaltenes, carbenes and carboids, complex bodies which probably represent a series of increasingly polymerized or condensed cyclic hydrocarbons.[2] The close resemblance of petroleum and natural asphalts both in composition and in applicability is pointed out by Marcusson.[3] In general, natural asphalts show a relatively high proportion of mineral constituents whereas petroleum asphalts contain less than 1 per cent. Furthermore, free asphaltogenic acids are present in the latter only in small quantities, if at all. Petroleum asphalts, on the other hand, contain a much larger proportion of oily constituents, often 40 to 80 per cent. The consistency of the latter, however, varies considerably, depending upon the source of the asphalt and its subsequent treatment.

In this chapter discussion will be limited to the preparation, properties and uses of petroleum asphalt, that is, those materials obtained in the refining of various petroleum distillates or residues, or by treatment of the latter as, for example, by oxidation.

OILY CONSTITUENTS

These have been described as thick, fluorescent oils, consisting of unsaturated and saturated hydrocarbons, the latter being probably mainly naphthenes or polynaphthenes.[4] Mack[5] considers that these oily bodies form an essential part of asphalts and influence to a high degree the properties of the latter substances. He found that asphaltenes swelled on being heated in contact with oils derived from asphalts of high susceptibility (*q.v.*) to temperature changes. On continued heating, solution was effected. However, the oleaginous liquids, except those containing a high proportion of sulphur compounds, from asphalts of low susceptibility were non-solvents for asphaltenes. The physical properties of oils from several different asphalts are given in Table 217. Those liquids having a high viscosity-gravity constant,[5a] specific gravities and refractive indices (indicating the presence of cyclic hydrocarbons) were good solvents for asphaltenes. Those oils (particularly samples B and C) for which these values were low were poor solvents.

One procedure for isolating the oily portion of asphalts comprises treatment of the specimen with 88°Bé. straight-run naphtha, filtering the insoluble material, and evaporating the naphtha from the filtrate.[6] The non-volatile liquids thus obtained are absorbed by about five times their weight of fuller's earth and the latter then extracted with the naphtha. Evaporation of the solvent yields the oily constituents.

It is interesting to note that stable, water-white hydrocarbons have been prepared from Trinidad asphalt.[7] The procedure consisted in treating the asphalt with petroleum ether (boiling below 50°C.) thus effecting separation into soluble petrolene hydrocarbons and insoluble asphaltenes. The latter were removed by filtration and the solution then subjected to the action of fuller's earth to eliminate resinous materials. Petrolene hydrocarbons were recovered by vacuum evaporation of the solvent. The extract thus obtained was dark olive green in color. This was then distilled (at pressure less than 1 mm.) and two fractions taken over, one boiling at —69 to 135°C. and the other at 135 to 185°C. The undistilled residue was almost solid at room temperature.

The lower boiling fraction was treated repeatedly with an equal volume of 98 per cent sulphuric acid until the acid layer had only a pale red color. The oil layer was then washed with water, dehydrated over metallic sodium, and redistilled *in vacuo*. A water-white distillate was secured. The higher-boiling fraction, after dilution with petroleum ether (previously acid-treated) was subjected to the action of sulphuric acid, washed with water, dried over sodium, and the ether evaporated under reduced pressure. Distillation *in vacuo* of this refined fraction yielded a water-white, nonfluorescent distillate.

The third fraction, or undistilled residue, also was diluted with petroleum ether, washed successively with sulphuric acid and water, freed from solvent, dried and distilled (*in vacuo*) to a boiling point of 263°C. During acid treatment in this instance a tarry layer separated. The latter, after refining as outlined, also yielded a water-white distillate.

[5a] This is given by the relation

$$A = \frac{G - 0.24 - 0.022 \log(V - 35.5)}{0.755}$$

in which A is the constant, G the specific gravity at 60°F. and V the viscosity in seconds (Saybolt) at 210°F. For a discussion of this constant see J. B. Hill and H. B. Coats, *Ind. Eng. Chem.*, 1928, 20, 641.

RESINS

The chemical properties and structures of the resinous and asphaltic constituents of petroleum are imperfectly known and their separation from oils is accomplished by empirical methods based on their insolubility in various solvents. According to Holde and Eickmann[7a] four types of substances may be obtained:

(1) Hard asphalt by precipitation with benzine (sp.gr. 0.70). From sulphur-containing oils this appears to be a variety of asphaltum.
(2) Softer asphalt by the use of an alcohol-ethel mixture. The proportion of insoluble material is greater with this solvent than with benzine.
(3) Amyl alcohol precipitates not only the same materials as alcohol-ether mixture, but in addition a large amount of resinous materials. This solvent has been proposed for the preparation of lubricating oils free of asphaltic and resinous materials.[8]
(4) Extraction of resinous materials with 70 per cent alcohol.

The resinous materials obtained from a machine oil distillate with the last-named solvent had oxygen contents greater than the original oil, gravity was greater than 1 and iodine number of 15 to 26 as compared with 7.6 for the oil.[9] Furthermore, they contained 11.8 per cent of saponifiable constituents. Other solvents which may be employed for the extraction of such resins, particularly from lubricating or turbine oil distillates, are acetone or castor oil,[10] or a mixture of methyl alcohol and a hydroaromatic hydrocarbon, e.g., cyclohexane.[11]

Adsorption agents, for example animal charcoal or Florida earth, may be substituted for solvents.[12] As an illustration, mazout is treated with bone charcoal, which is freed afterwards from oil by washing with benzine, and then extracted successively with 70 per cent ethyl alcohol, amyl alcohol, ether, benzene and chloroform. In this manner partial fractionation of the resins was effected as indicated by the density, iodine number, sulphur content and molecular weights (given in Table 218) of the extracts.

TABLE 218. —*Characteristics of Resins from Mazout.*

Solvent	*d*	Extract Iodine Number	% Sulphur	Molecular Weight
Ethyl alcohol	1.0867	8.06	0.55	1588
Amyl alcohol . . .	1.059	16.23	1 02	1261
Ether.	1.044	32 31	2.11	801
Benzene	1 110	- -		-
Chloroform	1.077	-	-	

According to Vasiliev and Zhirnova,[13] silica gel is a much better adsorption agent than fuller's earth as the latter extracts only about 20 per cent as much resin and also effects polymerization.[14] After removal of asphaltogenic acids (with caustic soda) and asphaltenes (with benzine), these investigators treated petroleum distillates with silica gel at 50°C. The gel was then freed from oil with benzene, and the resins extracted with chloroform or a mixture of benzene and ethyl alcohol. The neutral products obtained in this manner exhibited molecular weights (in benzene) varying from 290 to 788, as compared with 5000-6000 for asphaltenes. The formulas of the resins appeared to be $C_nH_{2n-m}O_2$ in which n ranged from 16 to 69 and m from 8 to 48. This suggested that the compounds possessed a highly polycyclic structure which was only slightly unsaturated. The resins were easily converted to asphaltenes by oxidation which resulted in the removal of hydrogen and further condensation. Treatment with sulphuric acid yielded asphaltenes and sulphonated bodies.

In connection with the polycyclic nature of resins, it is interesting to note that extraction with benzine of the orange-colored, resinous, oily residue from the distillation of crude petroleum yielded a yellow crystalline hydrocarbon.[15] This hydrocarbon exhibited a spectrum similar to that of anthracene, had a specific gravity of 1.204, and melted at 420-430°C. Heated to higher temperatures it sublimed and distilled, giving off brilliant yellow fumes. It was designated petrozcene to indicate its polycyclic structure.

Resin-like bodies formed during the distillation of petroleum were examined by Siebeneck.[16] He reported that these distil over at 400°C. with steam in about a 0.3 per cent yield on the crude oil, have specific gravities greater than 1, softening points of about 45°C. and flow points about 60°C. They are partially soluble in benzine but completely so in benzene or other aromatic hydrocarbon solvents. The crude materials may be fractionated by steam distillation to give products of somewhat higher softening and flow points. Subjected to cracking distillation they yield paraffin oil and coke.

The resinous components of lubricating oils, although present to only a few tenths of a per cent, are solid, oxygenated, lac-like bodies.[17] Removal of these by an alcohol-ether mixture appears to reduce the gumming tendency of the lubricants. A method of preparing resins of petroleum origin comprises distillation of heavy, residual hydrocarbons at low pressures, to remove oily constituents, and extraction with a hydrocarbon solvent, e.g., naphtha or kerosene, to eliminate asphaltenes.[18] Aqueous suspensions of such resins are suggested as sizing agents for paper, for impregnation of porous paper and for the manufacture of laminated paper and board.[18a] Since these resinous bodies appear to be composed only of hydrocarbons, emulsions or suspensions of them may be prepared with the aid of bentonite, sodium salts of petroleum sulphonic acids, or the sodium soaps of acids made by oxidation of paraffin wax.[19] Another application of these resins includes their incorporation with rubber, rubber latex, chicle, gutta-percha or balata to form a chewing gum base.[19a]

ASPHALTENES

These compounds are found in crude petroleum and its distillates, particularly the higher-boiling fractions and residuums, and are probably the result of condensation and polymerization of the aromatic constituents in the oil. The asphaltene content of such oils varies over a wide range, being 0.25 per cent in Grozny paraffin-free petroleum to 32.3 per cent in solid petroleum pitch.[20] Analysis of asphaltenes from one oil showed a content of 85.5 per cent carbon, 6.8 per cent hydrogen and 7.7 per cent oxygen and sulphur. Air-blowing of a tar oil at 350°C. did not alter the composition or properties of the asphaltenes though it did increase their proportion from 13.7 to 32.3 per cent. Similarly, oxidation of (Weitzer) crude oil at 120-130°C. resulted in the conversion of resins into these more complex bodies.[21] Reaction in this instance was not accelerated by manganese dioxide or fuller's earth, as these catalysts were probably poisoned by sulphur compounds. According to Rogers and Shoemaker,[22] oxidation tests for the stability of lubricating oils are a measure of the time required (under specified conditions) for the rapid formation of asphaltenes. Compounds having compositions corresponding to 71.6 per cent carbon, 6.3 per cent hydrogen, 13.3 per cent oxygen and 8.1 per cent sulphur have been prepared by heating paraffins and naphthenes with sulphur and oxidizing with air.[23]

[19a] Carleton Ellis, U. S. P. 1,976,774, Oct. 16, 1934, to Standard Oil Development Co.

With respect to the composition of asphaltenes, it is interesting to note that Nellensteyn[24] reports the following analysis of such bodies derived from asphaltic material (from Mohenjo-Daro) thought to be 5000 years old: carbon 78.2 to 78.7 per cent, sulphur 7.1 to 7.4 per cent, hydrogen 3 to 7.7 per cent, nitrogen 0.7 to 1.2 per cent, and oxygen 0.68 to 1.7 per cent.

According to Sakhanov,[25] asphaltenes are soluble in aromatic hydrocarbons, carbon disulphide,[25a] chloroform and carbon tetrachloride, and dissolution is accompanied by evolution of heat and by swelling whereby they are changed from hard, brittle particles to viscous, tough masses. The latter are highly dispersed colloidal solutions, and are as stable as aqueous gelatin solutions. Asphaltenes are lyophilic with respect to aromatic or halogenated hydrocarbons, carbon disulphide and petroleum tars, but lyophobic in relation to paraffins and naphthenes. Natural asphalts and petroleum pitch are probably solutions of asphaltenes in resins and heavy oils.

Chernozhukov[26] concluded from his experiments that the presence of sulphur compounds in oils during oxidation is essential for the formation of asphaltenes. Treatment of liquid paraffin with oxygen under 15 atmospheres pressure for 4 hours at 150°C. or with oxygen under 12 atmospheres pressure for 2 hours at 250°C. yielded on dilution with petroleum ether either a white precipitate or a light yellow flaky sediment, respectively. No asphaltenes or carbenes were noted in either case. On the other hand sulphur-containing distillates (turbine and spindle oils) from Balakhanui, Grozny or Emba crudes yielded asphaltenes having compositions corresponding to $C_{172}H_{176}O_{14}S$ and $C_{130}H_{142}O_{12}S$. Also white oils, after heating with sulphur, oxidizing under pressure and dilution with petroleum ether, gave insoluble bodies. When these were heated to 100°C. they furnished asphalt-like bodies apparently having the formula $(C_{24}H_{27}O_3S)_x$. It has been reported also that the resinous deposits obtained from Boryslaw (Galicia) paraffin oil, on storage, had a sulphur content of 2.5 per cent whereas the oils had only 0.1 per cent sulphur.[27]

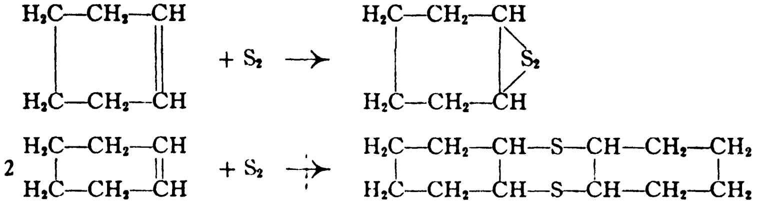
Spielmann[28] points out that since asphaltenes and resins are considered to be polycyclic bodies containing sulphur or oxygen, and both of these elements can exist in ring formations, such compounds may result from reactions indicated by



Asphaltenes react with sulphuric, or fuming sulphuric, acid to give oxonium compounds,[29] which are insoluble in water, unattacked by alkalies, but hydrolyzed (to sulphuric acid) by dilute hydrochloric acid.[30] With fuming nitric acid cyclic nitrogen derivatives (containing 4 to 6 per cent nitrogen) are obtained, which may be precipitated from an acetone solution by mercuric bromide or ferric chloride dissolved in ether. Alkalies transform them into water-soluble salts of isomeric isonitric acids.[31] The unsaturated character of asphaltenes is indicated by their reaction with halogens or halogen acids to give addition products. Also with chlorosulphonic acid they yield compounds containing both sulphur and chlorine. Oxidation with Caro's acid (monopersulphuric acid, H_2SO_5) of asphaltenes high in sulphur gives rise to sulphoxides and sulphones, while oxygen-containing compounds are produced from those low in sulphur. Nametkin and Putzillo,[32] however, report that perbenzoic acid reacts with asphaltenes but iodine does not.

As previously mentioned, benzine is employed for the precipitation of asphaltenes from petroleum distillates.[33] When this precipitant is used as an analytical reagent the following specifications are advocated for it:[34] d^{15} 0.695-0.705, a boiling range of 65-95°C., and not more than 2 per cent should be soluble in a

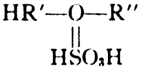
mixture of 80 parts of 96 per cent sulphuric acid and 20 parts of fuming acid (20 per cent SO_3). Garner[35] uses a benzine having d^{15} 0.680-0.690, aromatic hydrocarbon content of not more than 0.5 per cent and a distillation range (for at least 90 per cent) of 60-80°C. Other liquids which may serve as precipitants are acetone,[36] ethyl acetate[37] and methyl ethyl ketone saturated with water.[38] It is also reported that cyclohexane is not a satisfactory reagent since it dissolves a large proportion of the substances insoluble in benzine.[39] Nellensteyn and Roodenburg[40] propose ethyl ether as it is a homogeneous substance, does not require standardization and has a greater solvent power for hydroxy acids (due to oxidation) in asphalts than low-boiling hydrocarbons.

Removal of asphaltenes and other dark-colored substances from natural or artificial asphalts furnishes products which may be used in the manufacture of asphalt paper, lacquers, varnishes or paints.[41] The refining procedure consists in the addition of a liquid precipitant, such as pentane or aromatic-free gasoline. The asphalt solution may then be further treated with decolorizing agents, such as bleaching earths. Other agents which may be employed include sulphuric acid, anhydrous aluminum or ferric chloride, or boron fluoride.[41a] The latter materials are said to convert any dissolved asphaltenes into insoluble substances. In the case of mineral oils, warm dilute sulphuric acid (1 to 10 per cent)[42] may be used, or the liquid is allowed to stand in contact with aqueous solutions of heavy-metal salts, especially the chlorides.[43]

According to Rakovskii and Balashov,[44] 50 per cent sulphuric acid is the best strength for precipitation of asphaltenes from tar (from Pintsch retorts). In this instance the products are contaminated with phenols which may be separated by steam distillation.[45] In some instances, however, asphaltenes from acid sludges are reported to differ from normal asphaltenes in being soluble in basic solvents and being coagulated on heating to 100°C.[46] They are probably oxonium compounds derived from sulphuric acid. It is suggested that the composition for such derivatives may be represented by[47]



$$\begin{array}{c} HR'\text{—}O\text{—}R'' \\ \| \\ HSO_3H \end{array}$$

Hydrogenation of asphaltenes dissolved in hydrocarbon solvents converts them into resins or resin-like bodies.[48]

CARBENES

Such compounds have been described as those components of asphalt which are soluble in carbon disulphide (and certain other solvents, e.g., nitrobenzene or pyridine) but not in carbon tetrachloride.[49] The test for these substances (difference in solubility of the sample in carbon disulphide and tetrachloride) was devised to detect those asphalts which had been injured by weathering or by severe heat treatment during either refining or production, as carbene-formation appears to take place at temperatures of around 700° F.[50]

MacKenzie[51] observed that the quantity of carbenes (insoluble portion) increased when a solution of asphalt in carbon tetrachloride was allowed to stand and also when the solution was exposed to light. He suggested that "pure carbenes" be defined as those which are precipitated from carbon tetrachloride solution after 12 hours in the dark. "Pseudo carbenes" are those precipitated on exposure of the tetrachloride solution to light, generally for periods greater than 12 hours. He proposed the following theory: "That light acting upon a solution of bitumen in tetrachloride causes the bitumen to decompose, the tetrachloride giving hydrochloric acid, which in turn combines with unsaturated hydrocarbons and precipitates them." Both types of carbenes contained 3 to 4 per cent chlorine, and also nitrogen and sulphur. "Pure carbenes" did not melt at red-heat while the pseudo variety melted with effervescence at temperatures above 300°C. The effect of light, as mentioned by Mackenzie, was also noted by Alexander.[52]

The following procedure is suggested for determining carbenes in brown-coal generator tar:[53] 2 grams of the tar are dissolved in 30 cc. of benzene and to this solution (at 50°C.) are added 100-150 cc. benzine. The precipitate, after washing with benzine and drying, includes asphalts and insoluble material. The asphalts are separated by extraction with acetone, and to the latter solution is added excess carbon tetrachloride. This liquid mixture is then distilled until the temperature nearly reaches 77°C. (to remove acetone), after which the insoluble carbenes are filtered, washed, dried and weighed. A method for estimating asphaltenes, carbenes and carboids by etching the sample with benzine, carbon disulphide or tetrachloride and examining under the microscope is described by Schwartz.[54]

Carbenes are black solids, resembling coal in appearance and, like asphaltenes, they react with sulphuric acid to give sulphur-containing acidic derivatives.[55] The latter are soluble in pyridine and the solution may be diluted with water. Addition of mineral acids or salts of calcium, iron or silver to such diluted solutions precipitate the free acids or the corresponding salts, respectively. The sulphur derivatives are hydrolyzed by boiling with water or dilute alkalies with the liberation of sulphuric acid, but are stable towards alcoholic alkali.

CARBOIDS

These compounds are deep black in color like coal. In contrast to carbenes they are insoluble in carbon disulphide and probably represent a further stage in decomposition (polymerization or condensation) than carbenes.[56] Like the latter, carboids react with sulphuric acid to give acidic sulphur derivatives which are hydrolyzed by boiling with water or dilute hydrochloric acid. These sulphur compounds, however, are insoluble in pyridine and are decomposed by aqueous potassium hydroxide.

Not only are carboids isolated from natural or petroleum asphalts, but they are also formed during certain hydrogenation operations.[57] For example, in the hydrogenation of shale tar (boiling 230-340°C.) the optimum temperature was found to be 440°C. since higher temperatures accelerated formation of carboids and coke.[58] Hydrogen pressure also exerts a considerable influence, lower pressures favoring the development of these bodies.[59]

ASPHALTOGENIC ACIDS

In addition to the four main constituents of asphalts previously mentioned, i.e., petroleum resins, asphaltenes, carbenes and carboids, another type of compounds present are the asphaltogenic acids or their anhydrides.[60] These are described as tar-like or resinous masses which are soluble in alcohol or chloroform, but nearly insoluble in petroleum ether. Their sodium salts are also sparingly soluble. The acids usually exhibit a specific gravity greater than 1, and contain variable proportions of sulphur. By continued heating at 200°C. they are transformed into the corresponding anhydrides and at higher temperatures substances resembling asphaltenes are formed. A comparison of the properties of some acids from Trinidad crude and from a Texas oil heated for 70 hours at 120°C., in air, is given in Table 219.

TABLE 219.—*Properties of Asphaltogenic Acids from Trinidad Crude Asphalt and from Heated Texas Oil.*

Acids from	Solubility in Petroleum Ether	Acid Value	Saponification Value	Iodine Value	Sulphur %
Trinidad crude asphalt .	Nearly insoluble	98.5	120 4	22.4	3 1
Texas oil.............	Nearly insoluble	89.3	147.0	17.3	1.2

The acids may be isolated in the following manner: The bitumen is dissolved in benzene (5 times the volume of asphalt) and the solution treated with neutral alcohol (8 times the volume of benzene). In this manner most of the neutral constituents are precipitated. The benzene-alcohol solution is decanted, neutralized with sodium hydroxide and then diluted with an equal volume of water. Unsaponifiable constituents are extracted with benzene, and the aqueous solution concentrated on a water bath. Asphaltogenic acids are liberated by acidifying with a mineral acid.

To secure the acid anhydrides, the unsaponifiable portion is united with the pitch-like substances precipitated by alcohol (in the first operation) from the benzene solution, and the mixture saponified with alcoholic potassium hydroxide in the presence of benzene. The resulting alcoholic solution of potassium soaps is diluted with water, extracted with benzene, concentrated, and then acidified with a mineral acid.

The formation of asphaltogenic, or polynaphthenic, acids by air oxidation of

naphthene-containing petroleum distillates in the presence of alkali was observed by Charitschkov.[61] He described these acids as syrupy liquids, density 1.2, incapable of crystallizing, soluble in alcohol, chloroform, benzene, ether and carbon disulphide, and not being reduced by sodium amalgam. They gave a red coloration (like ketones) with sodium nitroprusside, reduced ammoniacal silver nitrate or Fehling's solution, and decomposed on distillation even under reduced pressure. As an example, oxidation of a kerosene fraction (boiling 169-171°C.), containing mainly one of the isomeric decanaphthenes, yielded an acid of the formula $C_{20}H_{25}O_4$.[62] The acid $C_{24}H_{34}O_4$ was obtained similarly from another decanaphthene fraction (boiling 164-168°C.). These products furnished viscous esters and on exposure to air (particularly in the presence of alkalies) resinified to asphalt-like bodies. Hence the name asphaltogenic acids. Charitschkov believed that at least two of the four oxygen atoms (in each acid molecule) were in hydroxy groups, and to the latter he attributed the pseudo acidic properties of the compounds. The presence of an aldehyde group (CHO) could not be proven.

Staeger[63] reports that asphaltogenic acids are obtained as some of the oxidation products of transformer oils. In agreement with Charitschkov, he considers them to be highly unsaturated, dihydroxy monocarboxylic acids. The exceptions appear to be the monohydroxy monocarboxylic acids resulting from the oxidation of mineral oils in the presence of lead as a catalyst. Rodman[64] and Brauen[65] observed the presence of polynaphthenic acids in transformer oils which had been subjected to long continual use. The latter investigator found the saponification number[66] of such bodies to be 187 and their molecular weights about 600.

It is interesting to note that a toxic effect of plant sprays (containing petroleum hydrocarbons) to foliage is ascribed by Tucker[67] to oil-soluble asphaltogenic acids. The latter are oxidation products resulting from the action of air and light on unsaturated hydrocarbons present in the spray. He believes that this toxic property can be attributed to the greater ease with which these acids pass through the walls of the leaf cell than the unoxidized oily portion and to their further breakdown into colloidal asphaltic bodies during which they absorb oxygen from the cells which they surround or into which they have gained entrance. Only a small proportion of acids (about 0.5 per cent) is required before injury to the foliage is apparent. Tucker suggests, therefore, that only oils having a low olefin content be employed in spray compositions and furthermore that such oils should be examined with respect to their resistance to oxidation in light.

ASPHALTS AS COLLOIDAL SYSTEMS

It is generally conceded that asphalts are colloidal systems but there are considerable differences of opinion as to the constitution of such systems. Sakhanov[68] suggested that asphalts are colloidal solutions of asphaltenes in tars and heavy oils and furthermore that carbenes and carboids are colloidal modifications of asphaltenes.[69] The latter being lyophilic with respect to aromatic hydrocarbons, terpenes, chlorinated hydrocarbons and carbon disulphide are dissolved by them forming highly dispersed and stable systems. On the other hand, as stated previously asphaltenes are lyophobic toward paraffin hydrocarbons and naphthenes and are coagulated by these substances.

Nellensteyn[70] advances the theory that asphalts contain elemental carbon in colloidal form, the latter being the essential constituent. In other words, the asphaltene micella may be viewed as a carbon nucleus enveloped in hydrocarbons. Evidence for this was based on the synthesis of asphalt-like bodies (carbon organosols) by the electrical dispersion of carbon in carbon tetrachloride, in this liquid containing 5 per cent of an asphalt-base oil or protective bodies extracted from asphalt, or in liquid paraffin or an asphalt-base oil distillate. Brown, stable sols were obtained whenever protective bodies were present, otherwise gray-black, unstable colloidal solutions resulted. However, the latter could be stabilized and the color changed to brown by incorporation of protective agents. Furthermore, the dispersed phase (after filtering off large particles which were always formed) could be separated by addition of benzine (boiling 40-60°C.).

Further substantiation of this theory was secured by ultramicroscopical examination of natural asphalt (from Trinidad) and Persian, Mexican and Borneo petroleum asphalts.[71] Of the three latter, the first was an oxidized asphalt and the other two were prepared by distillation of corresponding asphalt-base crude oils. All of the materials exhibited the Brownian movement, this being very slow when a viscous medium (lubricating oil) was employed, but intense when benzene, toluene or carbon disulphide was the diluent. As viewed under the ultramicroscope lyophobic ultramicrons appear to be strongly protected and assume the properties of lyophilic sols with regard to reversibility in solubility and decrease of sensitivity to flocculating agents. It was believed that in asphalt solutions there are present highly protected lyophobe sols, showing reversibility because of protectors, and the ultramiscroscopic image is due to lyophobe carbon particles.

If asphalt be considered as consisting of three principal groups of components:

1. the medium
2. a lyophile part: the protective bodies
3. a lyophobe part: the elemental carbon

and the dispersed phase (or asphalt micelles) consisting of the last two groups, then the stability of the system depends upon the relation between the micelles and oily medium. According to Nellensteyn[72] the most important factor affecting stability is the interfacial tension. When this is decreased (e.g., by the addition of benzine) flocculation or precipitation occurs due to the joining of particles of the dispersed phase. Liquids of low surface tension (17 to 24 dynes per cm.), such as benzine, ether, *n*-hexane or acetone, are flocculating agents. Those possessing higher surface tensions (27 to 36 dynes per cm.), such as benzol, carbon disulphide and pyridine, are peptizing agents. Nellensteyn points out that in the standardization of normal benzine as a precipitant (for the analysis of asphalts) its surface tension should be considered as well as its boiling range and gravity. He also believes that the action of carbon tetrachloride on carbenes (i.e., precipitation) may be explained by the fact that the surface tension of this chloride (25.7 dynes per cm.) places it in a class intermediate between precipitating and peptizing agents. For this reason the tetrachloride affects only the less stable micelles. The latter would be formed by decomposition as for example by overheating, distillation or air-blowing.

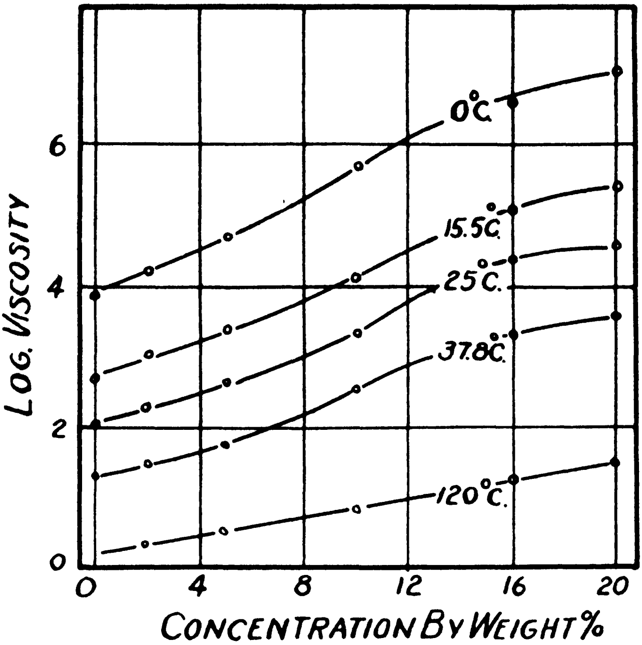
Pfeiffer and van Doormaal[73] agree with other investigators that asphalts may be considered as colloidal systems, and suggest that the latter consist of asphaltenes dispersed in maltenes.[74] These two constituents may be readily separated by treatment of asphalt with benzine (boiling 60 to 80°C.). The dispersed phase or asphaltenes (benzine-insoluble) are believed to consist of high-molecular hydrocarbons which are predominantly aromatic or hydroaromatic in character, having a comparatively low hydrogen content, and formed by polymerization and dehydrogenation of lower-molecular hydrocarbons. The dispersing medium or maltenes (benzine-soluble portion) governs the rheological properties of asphalts.



Courtesy Journal of Physical Chemistry

FIG. 299.—Concentration Plotted Against Logarithm of Viscosity for Solutions of Asphaltenes in Petrolenes. Viscosity at 120°C. in poises; others in g.sec.cm.$^{-2}$ (C. Mack)

When the maltenes are highly aromatic (or hydroaromatic) the asphaltenes are so well peptized that the resulting compositions flow readily and can be classed as purely viscous materials. Maltenes of slightly lower peptizing power give rise to products which exhibit a somewhat plastic character and which may be designated as normal types. If the peptizing action of the dispersing medium be further reduced, due either to low aromatic content of the crude oil serving as the source material or to the elimination of aromatics and hydroaromatics by air-blowing, then the resulting asphalt has a strongly plastic character.

These conclusions were substantiated (at least in part) by extracting maltenes from asphalts representing the three classes mentioned above. Asphaltenes of the same type were then dissolved in each of three maltenes. In each instance the rheological property of the asphalt so-made corresponded to that shown by the sample from which the maltenes were obtained initially.

[74] Maltenes are also known as petrolenes.

According to Mack,[75] petroleum asphalts may be considered as a dispersion (lyophilic sol) of asphaltenes in petrolenes (asphaltic resins and oily constituents), though carbenes, carboids and asphaltic acids (or their anhydrides) may be present also in small proportions. Viscosity measurements, particularly relative viscosities, indicated, however, that at high temperatures (120°C.) liquid asphalts behaved as ideal solutions. Such measurements were made on solutions (in the same petrolenes) of asphaltenes derived from asphalt by precipitation with petroleum ether.[76] The falling cylinder method was employed.[77] The apparatus consisted of two vertical coaxial cylinders. Asphalt was placed between the cylinders, weights placed on the outer cylinder and the velocity with which it moved was measured. Viscosity was calculated according to the formula

$$N = \frac{P}{2\,LV}\ln\frac{R_2}{R_1}$$

in which N = the viscosity in poises, P = total weight, V = velocity, L = height of asphalt, and R_2 and R_1 = radii of the outer and inner cylinders, respectively.[78]

The viscosity of solutions of asphalts, varying in concentration from 2 to 20 per cent, are shown graphically in Fig. 299. Relative viscosities, i.e., the viscosity of the solution divided by that of the solvent, are given in Table 220.

TABLE 220.—*Relative Viscosities of Solutions of Asphaltenes in Petrolenes.*

% Concentration	Relative Viscosities at 0°C.	15.5°C.	25°C.	37.8°C.	120°C.
2	2.137	2.136	1.82	1.552	1.353
5	6.76	5.281	4.23	3.00	2.09
10	71.82	28.81	20.01	19.37	4.312
16	596.4	294.1	201.8	116.2	11.45
20	1792.3	592.9	367.0	224.2	20.12

Mack has also shown that the molecular weight of the solute (asphaltenes) may be calculated from the relative viscosity by application of the formula

$$\log \textit{relative viscosity} = kcM$$

in which k is a constant, c is concentration in per cent by weight, and M is the molecular weight. By the use of this equation and the above data, the molecular weight of the asphaltenes investigated was shown to be 1800 at 120°C. (See Table 221.) At lower temperatures the values ranged from about 3000 to 5000.[79] Mack believes these latter values can be attributed to association of the asphaltene molecules. Furthermore, this phenomenon (association) is responsible for the high relative viscosities (at low temperatures) rather than solvation.

PREPARATION OF ASPHALT FROM PETROLEUM

As previously mentioned, the high-boiling residues from distillation or cracking operations are the source of petroleum asphalts. The quality of the product so

prepared is affected by the distillation operation and by the presence of free carbon.[80] When the latter is in a colloidal state it exerts no deleterious action, but if merely suspended (e.g., due to overheating during distillation) in the asphalt then an inferior product is the result. It is reported that the material made from asphaltic-base crudes in a shell still has a higher softening point than that made in a pipe still[81] for a given penetration of the asphalt. This may be accounted for by the low resin and asphaltene contents and high proportions of hard asphalt and coke. Paraffin base oils on straight distillation yield a residue consisting of oil, asphalt, coke and solid paraffins, the latter being disadvantageous if the percentage of resins and asphaltenes is low.[82] Such oils, however, furnish satisfactory asphalts if they are first subjected to mild cracking, that is not severe enough to form coke.

Ichikawa[83] reports that in the steam-refining of petroleum asphaltic residua much better products, especially with respect to cementing and tensile strengths, are obtained if a large rather than a small volume of steam is employed. Distillation at low pressure (2 mm.), however, was considered as the best method of manufacture.

Egloff and Morrell[84] point out that cracking can be controlled so as to permit production (10 to 20 per cent) of asphalt in addition to high yields of gasoline from paraffin-base charging stocks (e.g., Pennsylvania crude oils) which have low sulphur contents. Because of the absence of this latter element, and also oxygen, they believe that under these conditions asphalt formation is the result of condensation and polymerization accompanied by dehydrogenation. By subsequent blowing operations (with air or steam) the cracked asphaltic residues can be made to meet many specifications.

Another procedure for making asphalt includes dissolving the oil, or distillation residues, in liquid aliphatic esters or ethers, and then cooling the mixture so that both the paraffin wax and hard asphalt are precipitated.[85] Ethyl acetate, methyl butyrate or propionate or diisopropyl ether are appropriate liquids. After separation of the insoluble portion by filtration the liquid can be subjected to distillation to secure the soft asphalt.

The effects of continuous heating, for 70 days at 170°C., on the properties of two asphalts (m.p. 32.8°C. and 41.1°C.) from Mid-Continent crudes were investigated by Sikes and Corey.[86] They found that the acid value, after an initial increase, decreased considerably, which may be attributed to loss of volatile acids. Ductility and penetration also decreased rapidly while an increase was noted in the softening point and viscosity. The flash point was not altered much, and the solubility of the asphalt in carbon disulphide remained between 99.6 and 99.9 per cent.

Low-boiling petroleum hydrocarbons, e.g., benzine, have been proposed as solvents for the extraction of heavy oils from petroleum asphalts.[87] According to Stratford and Pokorny,[88] such light hydrocarbons may be admixed with methyl, ethyl, propyl, isopropyl or cyclic alcohols. Zwergal[89] treated asphalts with methyl, ethyl, propyl, butyl and amyl alcohols successively. He observed that the extracts obtained with the first two alcohols were oily and resinous, while those with the last two were coke-like. Those constituents which were soluble in propyl alcohol possessed the highest carbon and hydrogen and lowest sulphur and oxygen contents, and exhibited the highest ductility.

FIG. 300.—Plant for Deasphalting and Dewaxing with Liquid Propane. Tall column at left is for deasphalting; unit at right is for dewaxing.

Treatment of asphaltic oils with a normally gaseous hydrocarbon,[90] e.g., propane,[91] at temperatures and pressures at which the latter is liquid, results in the precipitation of asphalt.[92] This product is said to have a lower carbene content and higher solubility in naphtha (86°Bé.) than that obtained by distillation of the oil. When both wax and asphalt are present in the petroleum fraction, after precipitation of asphalt the pressure is released and some propane evaporated, thus chilling the oil and effecting separation of wax.[93] Following removal of the oil, the mixed precipitate is treated with liquid propane at a temperature sufficiently high to dissolve the wax. By adjusting conditions and methods of treatment of this type of oil, asphalt and wax can be precipitated separately or simultaneously.[94] Also, separation of soft and hard asphalts may be made in this manner.[95] Fractions of petroleum oils, resins and asphaltenes, obtained by treatment of petroleum residues with propane, may be remixed in proper proportions to give asphalts of the desired physical properties.[96]

[90] For use of natural gas under pressure to fractionate crude oil or heavy residues into asphalts, resins and oils, see S. v. Pilat, *Przemysl Naftowy*, 1935, 10, 661; *Chem. Abs.*, 1936, 30, 6542.

Instead of using liquefied propane alone, the solvent may consist of this hydrocarbon and approximately 40 per cent of ethane.[96a] Partial precipitation of asphalt and complete elimination of wax are secured by dilution of distillates (from hydrogenation operations) with 20 per cent by weight of liquid butane.[97] von Pilat[98] reports that a liquid, propane-butane mixture (61.2 per cent propane, 34.36 per cent isobutane and 4.17 per cent *n*-butane) removed only part of the asphalt from petroleum residues. By introducing dry natural gas, containing about 97 per cent methane, into the liquid mixture (until the pressure had risen to 30 atmospheres) almost complete separation of asphalt took place. Continued introduction of methane, until the pressure increased to 130 atmospheres, effected a step-wise fractionation of the oily portion, the higher-molecular weight hydrocarbons separating first and then those of lower molecular weights as the proportion of methane was increased.[99]

Ellis[99a] suggests treatment of hydrocarbon oils by mixing a stream of such oils with a stream of liquefied hydrocarbon gases (e.g., 75 per cent propane and 25 per cent ethane) at 20 atmospheres pressure and 75°F. to cause precipitation of asphaltic bodies, subsequently cooling the treated oil solution to about 20° to — 10°F. to remove wax and then releasing the pressure to rid the oil of the liquefied gas.

[99a] Carleton Ellis, U. S. P. 2,081,174, May 25, 1937, to Standard Oil Development Co.

Other extractants proposed include phenol, furfural,[100] cyclic nitrogen compounds, e.g., pyrroles, indoles, quinolines or piperidines,[101] and mixtures of secondary or tertiary aliphatic alcohols, e.g., *ter*-butyl, with water, alcohols or ketones.[102] Such aliphatic ethers as ethyl, isopropyl, butyl or amyl and esters of the corresponding alcohols with the lower fatty acids (formic to capric) are said to act as selective solvents for soft asphalt constituents, causing precipitation of the hard asphalt resin and also paraffin wax.[103] For obtaining high-grade asphalt from Mid-Continent crude oils it is suggested that residua from such crudes, containing constituents heavier than gas oil, be subjected to selective solvent action of furfural, nitrobenzene or sulphur dioxide, the insoluble portion furnishing lubricating oil stock and the soluble fraction a source of asphalt.[104]

OXIDIZED ASPHALTS

Oxidation, or air blowing, is often found to be the most desirable method of finishing many of the asphalts obtained from petroleum.[105] The exact nature of the reactions taking place during such operations is not definitely known and there is need of considerable investigation in this direction. Lahocinski[106] oxidized asphalts (from Polish crude oils) which he considered to consist of resins, asphaltenes and oil plus paraffin wax. Although the materials contained different proportions of the three ingredients, nevertheless the effect in each instance was the same, viz., diminution of the oil and resin contents and an increase of the asphaltene fraction. The latter influenced the melting point of the asphalt. He believed that the resin fraction was the carrier of all fundamental properties of asphalt, while the oil fraction exhibited no such characteristic properties.

Thurston and Knowles[107] have investigated the oxygen absorption of various constituents of asphalt (238 penetration at 25°C.) from Mexican petroleum. The following method of separation was employed. *Asphaltous acids and anhydrides* were extracted by dissolving the specimen in benzene and refluxing with aqueous alcoholic potash. Afterwards the alcohol layer was separated, acidified and the acids dissolved in ether. Evaporation of the latter yielded a brown, sticky mass. *Asphaltenes* were obtained by precipitation with straight-run Pennsylvania naphtha (88°Bé.) using 40 volumes to 1 of asphalt. Extraction of the precipitate with more naphtha eliminated occluded resins. Asphaltenes do not melt but swell and decompose on heating. According to Thurston and Knowles, asphaltenes are the essential constituents of asphalt, distinguishing it from other petroleum products, and are responsible for its plastic properties.

After separation of acids and asphaltenes, the remaining "petrolenes" were treated with fuller's earth, and the latter then extracted successively with naphtha, carbon disulphide and benzene to secure *oils, petroleum resins* and *asphaltic resins,* respectively. Both of these resins have moderate drying properties when exposed to air in thin films, and this is more pronounced with asphaltic resins which are the heavier and more viscous. No *carbenes* or *carboids* were present in the specimen tested. The analytic data are summarized in Table 222.

The rates of absorption of oxygen by the asphalt and also its constituents were measured (using 1 g. samples mixed with sand, at 200°C. for 3 hours) and these increased progressively with oily constituents, petroleum resins, asphaltic resins and asphaltenes. Also the quantity of oxygen absorbed was determined, and that recovered as water or carbon dioxide. Asphaltenes proved to be the most readily oxidized and oils the most resistant. Data obtained in the latter instance are given in Table 223. Some oxygen was used in the formation of alcohols, aldehydes and ketones, which were not measured but included under the heading "unaccounted for." Asphaltenes from oxidized asphalts did not react with oxygen any more readily than those from soft asphalts. Those obtained from air-blown cracked residuum, however, were the least reactive of any investigated.

TABLE 223.—*Oxidation of Constituents from Soft Mexican Asphalt.*

	Original Asphalt	Asphaltenes	Asphaltic Resins	Petroleum Resins	Oils
Oxidation:					
Oxygen used, % of sample	17.3	23.6	1.85	15.4	13.4
Change in weight, % of sample	−5.0	+2.7	−2.3	−3.67	−2.8

Recovered as CO_2	14.2	12.9	10.7	9.2	8.9
Unaccounted for	17.9	3.9	18.0	18.7	19.6

Thurston and Knowles suggest that oxidation may take place in three ways:

1. Addition of oxygen, which forms unstable compounds from which water is eliminated, leaving unsaturated compounds which polymerize.

2. Oxidation with the formation of carboxyl derivatives from which carbon dioxide is eliminated, followed by polymerization.

3. Elimination of volatile oxidation products other than water and carbon dioxide from the above types of unstable oxygen compounds, followed by polymerization.

These investigators also report that oxidation of asphaltenes results in the formation of carboids, 96 per cent conversion being obtained at 200°C. (for 3 hours) and 68 per cent at 150°C. In the absence of oxygen, at 150°C., 7 per cent transformation was effected. This indicated that oxidation and not merely heat polymerization was the essential reaction. Typical analyses of asphaltenes (from hard steam-reduced Mexican asphalt) and of the carboids from them by oxidation are given in Table 224.

TABLE 224.—*Asphaltenes and Carboids from Steam-reduced Mexican Asphalt.*

	Asphaltenes	Carboids
Carbon	81.50	74.25
Hydrogen	7.50	5.13

Sol. in CS_2, %	99.7	3.0
C:H ratio	10.9	14.5
Saponification value	6.4	124
Acid value	3.0	4.0

That asphalts made by air oxidation do not contain carboids was explained on the basis that the usual conditions of oxidation are not as severe as those in the above tests. Furthermore, during treatment the asphaltenes are not isolated and exposed intimately to the action of oxygen but remain dissolved in oils and resins.

A number of methods, differing essentially in construction details, have been suggested for the preparation of oxidized asphalts. Manheimer[108] points out that oxidation in tanks requires long periods of time, only a moderate period in batch stills, a short time in continuous shell stills, and is effected quickest in towers. The fundamental factors are (1) temperature, (2) air-blast, (3) nature of the initial product, (4) the oxidation surface, (5) carbon separation and (6) height of the liquid column. The temperature required varies with the composition of the charging stock, an average of 235-260°C. for paraffin base, 230-245°C. for asphalt base, while 220°C. is sufficient if the charge has a large proportion of soft asphalt. In addition to asphalt, gas and gas oil are the main by-products.

Gard and Aldridge[109] suggest heating the oil in a still and circulating hot oil through a heat-exchanger and back into the still. Before entering the heat-exchanger air is introduced into the hot body of oil and at the same time steam is forced into the liquid through a perforated pipe in the bottom of the still. By controlling the rate of air and steam supply and the temperature by the heat-exchanger, asphalt of a desired melting point, penetration and ductility may be obtained. In another operation, the hot residuum from a pipe still is mixed with air, and then conducted into a reaction chamber.[110] The temperature in the latter is regulated by cooling coils through which a portion of feed stock is passed. The same effect is accomplished by adding a liquid heat-absorbing medium, such as water or oil, which has a boiling point lower than the reaction temperature.[111] Before subjection to oxidation the residuum may be blended with cylinder oil having a viscosity (at 99°C.) of 190 seconds Saybolt.[112]

After being heated to high temperatures (about 220°C.), the asphaltic petroleum residue is conducted through a series of compartments in each of which air is supplied below the surface of the liquid.[113] Any vapors formed are removed and passed through a condenser. Catalysts which may be employed include spent clarifying and decolorizing agents (e.g., clays) from petroleum oil refining[114] and sulphuric acid mixed with persulphates or perborates.[115] In the latter instance reaction may be effected at 130°C. More intimate contact between the reactants is secured by forcing air through a porous ceramic diaphragm (before mixing with the heated hydrocarbon) thus transforming it into a state of minute subdivision[116] or by passing atomized petroleum residuum countercurrent to a hot air stream.[117]

Stratford[118] proposes as raw material, for the manufacture of oxidized asphalts, the extracts obtained by treating petroleum oils with selective solvents, e.g., phenol, aniline, sulphur dioxide or furfural. Hydrocarbons procured in this manner may be subjected to air-blowing at 200°C. and under a pressure of 50 lbs. per sq. in.[119]

After oxidation at relatively low temperatures (175°C.) the asphaltic product is subsequently maintained at a higher temperature (350°C.) to effect polymerization of oil fractions.[120] The latter operation may be conducted under pressure sufficient to prevent distillation of vaporizable oil fractions. When cracked residuum, relatively high in unstable compounds insoluble in carbon tetrachloride, is heated and air-blown it may then be blended with uncracked residue which has been similarly treated.[121] In this manner unstable constituents are reported to be stabilized and their segregation inhibited.

Bray and Beckwith[122] treat oxidized asphalt with benzine or liquid propane to extract oily components. Afterwards the bitumen fraction may be mixed with an oil possessing different characteristics than that separated. Or the separated oil may be subjected to the action of liquid sulphur dioxide.[123] The extract thereby obtained is blended with the asphalt and the mixture is air-blown. In this way a product of high susceptibility to temperature changes is made.

The use of air containing a small proportion of chlorine is recommended by Douthett.[124] Asphalts are secured which have a high melting point for a given consistency and contain only about 0.5 per cent chlorine, but are free of undesirable non-volatile decomposition products.[125] Hoover[126] proposes adding a small pro-

portion of ammonia to the air for the purpose of reducing the olefin content and prolonging the adhesive life of the oxidized material.

PHYSICAL PROPERTIES OF PETROLEUM ASPHALTS

Possibly the more important characteristics of asphalts are their melting or softening points, penetration, viscosity and ductility.[126a] The softening point is determined generally by the ball and ring method. This comprises ascertaining the temperature at which a sample of asphalt, in a standard molded ring, will sag to a depth of 2.5 cm. under the weight of a small steel ball (of 0.375 in. diameter). A variation of this consists in placing 5 g. of mercury on a plug of asphalt (in a glass tube) and determining the temperature at which the mercury drops through the tube.[127]

Viscosity. The viscosity of an asphalt may be determined by any one of several methods,[128] including rate of flow through a capillary opening (Redwood, Saybolt or Ostwald viscosimeter), Couette rotating cylinder, and velocity with which a body of given weight sinks into the sample (e.g., Pochettino viscometer,[128a] previously mentioned). Traxler and Schweyer[129] found that this property was a linear function of the temperature between 15° and 35°C. and may be represented by the equation

$$\log\eta = at + \log b$$

in which η = viscosity in poises, T = temperature in °F., and a and n are constants. These investigators also suggest that the temperature susceptibility should be measured by the percentage decrease in viscosity for 1°C. temperature rise over this range. This value (also designated asphalt viscosity index or A.V.I.) may be calculated according to the formula

$$\text{A.V.I.} = 100[\eta_c/\eta_d(1/t_c - t_d) - 1]$$

in which η_c and η_d are the viscosities in poises at the temperatures t_c and t_d. Paraffin was is reported to lower the viscosity, and also adhesiveness, of asphaltic bitumen and the total quantity (including soft paraffin) should not exceed 5 per cent.[130]

Mitchell and Lee[131] call attention to the formula,

$$\eta T^n = a$$

in which η = viscosity in poises, T = temperature in °F., and a and n are constants. In its logarithmic form

$$\log\eta + n\log T = A$$

this indicates a straight line function between temperature and viscosity. Curves illustrating this linear relation are shown in Fig. 301 in which the logarithms of the temperature (°F.) are plotted against the logarithms of time of flow (in seconds) in a modified Ostwald viscosimeter.[132] Viscosity measurements at two, or better three, temperatures thus enable one to determine graphically the viscosity of the sample at any desired temperature. The slope of the line drawn through these points is equal to the value of *n*, and may be calculated according to the formula

$$n = \frac{\log\eta_1 - \log\eta_2}{\log T_2 - \log T_1}$$

in which η_1 and η_2 are viscosities in poises at temperatures (°F.) T_1 and T_2, respectively. This value *n* is also designated as the logarithmic temperature coefficient, and may be regarded as measure of susceptibility and is therefore a characteristic coefficient for the bitumen under consideration.

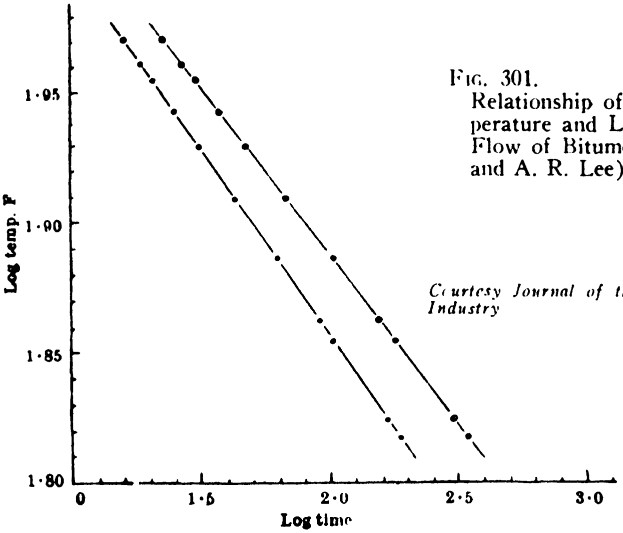

FIG. 301. Relationship of Logarithm of Temperature and Logarithm of Time of Flow of Bitumens. (J. G. Mitchell and A. R. Lee)

Courtesy Journal of the Society of Chemical Industry

Certain exceptions are tars having a low content of aromatics. In such instances the viscosity-temperature relation is represented by two intersecting straight lines, one for the lower temperature range and one for the upper. Such asphaltic bodies will, therefore, possess two logarithmic temperature coefficients, each characteristic over a particular temperature interval. An example of this is shown in Fig. 302.

Ductility. This is the distance (in cm.) which a briquette (of specified shape and dimensions) will stretch at 25°C. before breaking occurs, the rate of distention being 5 cm. per second. According to Müller and von Pilat[132a] asphaltene micelles are responsible for the very low ductility of some petroleum asphalts. This was indicated by the absence of these compounds in ductile asphalts, the increase in ductility (accompanied by increase in penetration) on their partial removal, and decreased ductility (and penetration) on their addition. Incorporation of an asphaltene solvent (e.g., naphthalene) increased ductility and penetration but lowered the softening point of asphalts, the optimum quantity being 7.5 per cent. Fulton and Kalichevsky[133] point out that blending tar resins substantially free of asphaltenes (and also oil) with low-grade asphalts improves the latter.

---

[132] This instrument is described by A. R. Lee, *J.S.C.I.*, 1934, **53**, 69T.

For a discussion on the testing of asphalts, see A. R. Lee and A. H. D. Markwick, *J.S.C.I.*, 1937, **56**, 146T.

Penetration. This is the depth in one-hundredths of a centimeter to which a standard needle pierces the sample under specified conditions of time, temperature and weight. Generally the weight applied is 50, 100 or 200 g., depending upon the temperature. Holmes, Collins and Child[134] state that two methods have been employed for expressing the susceptibility factor, or change in consistency, of asphalts with the temperature:

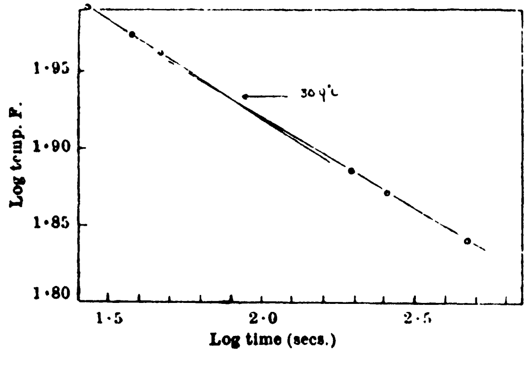

FIG. 302. Logarithmic Relationship of Temperature and Time of Flow for Tars of Low Aromatic Content. (J. G. Mitchell and A. R. Lee)

Courtesy Journal of the Society of Chemical Industry

$$\text{Susceptibility} = \frac{\text{penetration at } 46.1°\text{C.}/50 \text{ g.}/5 \text{ sec.} - \text{penetration at } 0°\text{C.}/200 \text{ g.}/60 \text{ sec.}}{\text{penetration at } 25°\text{C.}/100 \text{ g.}/5 \text{ sec.}} \quad (1)$$

$$\text{Susceptibility} = \frac{\text{penetration at } 37.8°\text{C.}/100 \text{ g.}/5 \text{ sec.}}{\text{penetration at } 25°\text{C.}/100 \text{ g.}/5 \text{ sec.}} \quad (2)$$

The first of these two, however, has been almost entirely supplanted by the second.

These investigators point out that no single method or factor has been developed which will serve to measure susceptibility over the desired range of consistency and temperature. They suggest three methods which can be used in conjunction with one another to give a fairly complete picture of the susceptibility characteristics of an asphalt.

Softening Point-Penetration Index. Correlation of data on the softening point and penetration of asphalts from a number of sources indicated that the following relation existed,

$$\log M = a \log P + \log k$$
$$\text{or } M = kP^a$$

in which M is the softening point (ball and ring) in °F., P is the penetration (at 25°C. per 100 g. per 5 sec.), and a and k are constants. Holmes, Collins and Child state that although the above relation gives no indication, by itself, of the change in consistency of an asphalt with temperature, nevertheless it is known (in a general manner) that the higher the penetration (at 25°C.) for a given softening point the less susceptible is the asphalt to temperature changes. To obtain more specific comparisons between different asphalts, a softening point-penetration index chart (Fig. 303) was developed, based on the same principle as that for a viscosity index chart for lubricating oils.[135] As standards, asphalt from heavy Mexican crude oil was chosen as 100 on the index scale and petroleum tar as 0. In the chart, the ordinates at the extreme left represent the penetrations (at 25°C. per 100 g. per 5 sec.) for petroleum tar and those on the heavy vertical line at 100 index for Mexican asphalt. Diagonal lines connecting these ordinates are the so-called iso-softening point lines. Thus, the straight line shown for 54.4°C. (130°F.) softening point is drawn between 19.5 and 57 penetration for petroleum tar and Mexican asphalt, respectively. The abscissas represent the index numbers.

FIG. 303.—Softening Point — Penetration Index Chart for Asphalts. (A. Holmes, J. O. Collins and W. C. Child)

As an example of the use of this chart, it is desired to determine the softening point-penetration index of an asphalt having a softening point of 54.4°C. (130°F.) and 40 penetration at 25°C. per 100 g. per 5 seconds. The penetration is read on the ordinate scale, and the horizontal line at this point is followed until it intersects the 54.4°C. (130°F.) iso-softening point line. At this point the index number is read from the abscissa scale (vertically downward) giving a value of 67.

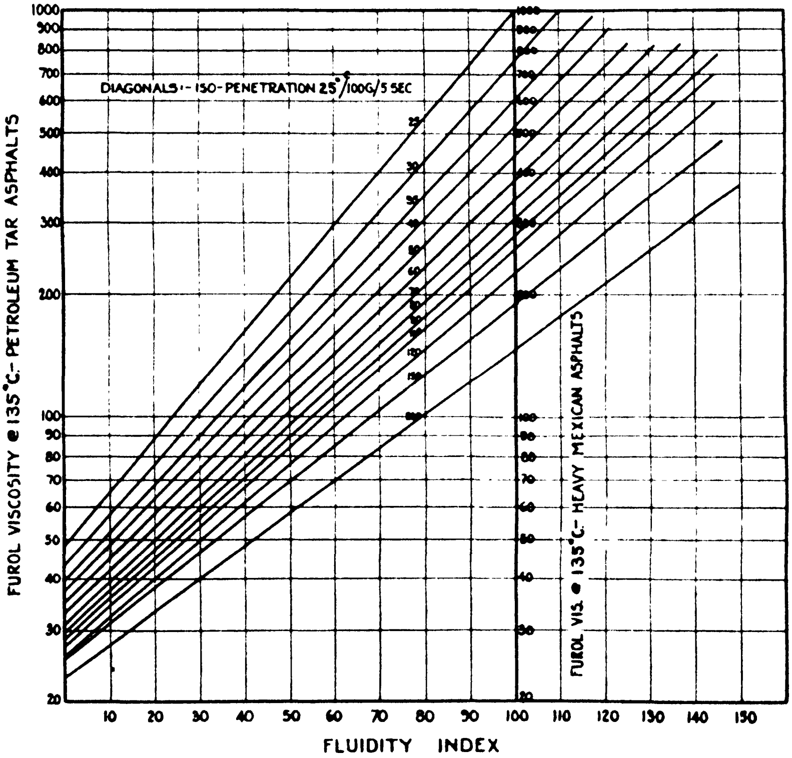
---

[135] For the viscosity index of lubricating oils, see E. W. Dean and G. H. Davis, *Chem. Met. Eng.*, 1929, 35, 618. Also Carleton Ellis, "The Chemistry of Petroleum Derivatives," The Chemical Catalog Co., Inc., New York, 1934.

Susceptibility Factor at Subnormal Temperatures. For temperatures below 25°C. (77°F.) the susceptibility factor may be expressed as:

$$\text{Susceptibility Factor} = \frac{\text{penetration at 25°C./100 g./5 sec.}}{\text{penetration at 0°C./200 g./60 sec.}}$$

The smaller the ratio of these two penetrations the lower, of course, is the change in consistency of the asphalt over this temperature range.



Courtesy Industrial and Engineering Chemistry

FIG. 304.—Chart for Fluidity Index of Asphalts. (A. Holmes, J. O. Collins and W. C. Child)

Fluidity Index. This was devised as a means of determining the susceptibility of asphalts at high temperature, and was developed in essentially the same manner as the softening point-penetration index except that the viscosity (seconds Furol) at 135°F. was substituted for the softening point. In the fluidity chart (Fig. 304) which can be employed in an analogous manner to the softening point-penetration chart, the ordinates are viscosity (Furol), the abscissas the fluidity index and the diagonal lines represent the penetration at 25°C. per 100 g. per 5 seconds.

An application of these three different values is shown by comparing the data (Table 225) obtained with asphalts having approximately the same penetration. For example, comparing Healdton and Colombian asphalts, it is seen that the former is less susceptible to normal temperature changes than Colombian, while the latter does not harden so rapidly (as indicated by the susceptibility factor) as Healdton at lower temperatures. Again, Mid-Continent and West Texas change in consistency to about the same degree at normal temperatures, but the former (as shown by fluidity index) is more readily affected by higher temperatures.[135a]

TABLE 225.—*Changes in Susceptibility Characteristics between Low and Elevated Temperatures*

Asphalt	Penetration at 25°C.	Softening Point-Penetration Index	Susceptibility Factor	Fluidity Index
Colombian	53	70	3.83	81
Healdton	55	73	6.11	—
Mid-Continent	50	63	3.92	85
West Texas	50	63	5.88	70

Pfeiffer and van Doormaal[136] report that the following relation

$$\log 800 - \log \text{penetration} = \alpha(t - 25°\text{C.})$$

exists between the penetration (25°C./100 g./5 sec.) and softening point (t) by the ball and ring method. The term α is characteristic of the susceptibility, and as it becomes greater or smaller the asphalt is designated as being correspondingly more or less sensitive to temperature change. To represent graphically the above relation and to furnish a means of classifying asphalts according to an index number, these investigators developed a nomogram (shown in Fig. 305) in which the ordinates are temperature and penetration and the diagonal represents the term α (or the susceptibility). Zero on the diagonal was chosen as the point at which the diagonal was intersected by a line connecting the softening point (40°C.) and penetration (200) for "not too heavy, steam refined Mexican bitumens." Division marks above and below the zero point were designated as + or —, respectively. A minus number indicated a high susceptibility index, a plus number the reverse.

According to this system, asphalts may be divided into three classes:

1. Those having an index between —1 and +1, and designated as the "N type" or normal asphalts. In this are included most steam refined bitumens generally used for road making.
2. Asphalts possessing an index number below —1 or the "Z type." These resemble coal-tar pitch in that they are characterized by great susceptibility and usually brittleness.
3. This class comprises bitumens exhibiting index numbers above +1, and are called the "R type." They possess low susceptibilities and only slight brittleness. The majority of blown-asphalts fall within this subdivision.

When asphalts are used in road construction, which constitutes their largest field of application, their efficiency as binding agents for stone and other mineral aggregates plays an important rôle. A study of the interfacial tensions between asphalts and solids has been made by Mack.[137] It was stated that when a liquid spreads over a solid surface two opposing forces are in play, one the adhesion of the liquid to the solid, and the other the cohesion of the liquid. The coefficient of

FIG. 305.—Diagram for Determining Penetration Index. (J. P. Pfeiffer and P. M. van Doormaal)

spreading was defined as the energy of adhesion minus the energy of cohesion. Spreading occurs only if this coefficient is positive.[138] Asphalts having a high spreading coefficient toward a solid exhibit a high degree of wettability for that solid and give a thin film which leads to increased adhesivity.

The interfacial tension of asphalt and mineral aggregates was measured by determining the volume of powdered material, (200 mesh) which settled out of benzene solutions of the asphalts on standing after the two components were shaken. It was assumed that there is a straight-line relationship between the settling volume of powders in asphalt solutions and the concentration of the latter, and thus by extrapolation the value for the asphalt itself was computed. The interfacial tensions were found to vary with the type of aggregate and also with the type of asphalt. Low coefficients of spreading and low energies of adhesion were observed for the asphalts against silica and high values against limestone and blue clay.[139] Geissler[140] reports that the greatest adhesion for bitumens is shown by stones of a hydrophobic character. When the latter are hydrophylic in nature there is a tendency for water to penetrate between the stone and the bitumen layer.

Lee[141] also considered the problem of adhesion of bituminous materials to stones for road construction, particular attention being given to the effect of moisture present on the stones. It was assumed that the degree of wetting of a solid by a liquid will depend on the nature of the latter, its viscosity (which influences the rate of spreading), the character of the solid and the texture and cleanliness of the surface. Tests showed that the wetting properties of road tar on highly polished, water-moistened surfaces of stones were not influenced to any great extent by the type of stone employed. Differences in wetting tendencies were found to be the result of various degrees of roughness, water being presumably trapped in the minute crevices of a rough surface and preventing wetting of the solid by the binder.

USES OF PETROLEUM ASPHALTS

As stated previously the principal application of asphalt is in the construction of roads, acting as a binder for a filler of broken stone or sand or both.[142] Frequently asphalts are not used alone but are mixed with various proportions of tars and heavy oils to obtain a material best suited for the problem at hand.[143] Other uses include employment in roofing and flooring compositions and as coating material either alone or in paints and varnishes. An interesting application is in asphalt mattresses which are laid on the banks and beds of rivers to resist erosion by river currents.[144]

For altering the flowing qualities and hardness of asphalt compositions it has been proposed to add phenols,[145] fatty acids, soap and tetralin,[146] naphthalene,[147] bleaching earths[148] and paraffins and ceresin waxes.[149] Various molding compositions include asphalt mixed with such fillers as powdered quartz,[150] fuller's earth, talc or slate[151] and hydrated magnesium silicate.[152] A proposed wallboard material contains asphaltenes incorporated with cement and cotton or asbestos.[153] For the purpose of preservation, ropes may be impregnated with a solution of asphalt and rubber to which graphite has been added as a lubricant.[154] Steam-refined petroleum asphalt has been proposed as a final coating material for rubberized fabric, an intermediate layer of varnish being applied to impart flexibility.[155]

ASPHALT EMULSIONS

Usual procedures for the application of asphalt as a protective coating consist in either heating until it becomes fluid and then applying in a molten condition or effecting a suspension in organic liquids (so-called "cutbacks"), e.g., naphtha, and brushing or spraying such compositions on surfaces to be covered. Later developments, however, comprise the preparation of aqueous emulsions of asphalts, usually with the aid of some emulsifying agent, followed by spreading such emulsions on the surfaces to be coated.[156] After evaporation of the water, the residual film is irreversible, i.e., will not re-emulsify when placed in water. Also it is ductile and resistant to flow under heat, this latter property being attributed to a gel or honeycomb structure.

According to Ross,[157] the proportions of ingredients may vary over a wide range, representative limits being 45 to 75 per cent asphalt, 25 to 55 per cent water, and 1 to 10 per cent emulsifying agent. However, as extreme examples as low as 30 per cent and as high as 95 per cent asphalt have been employed. As a rule the bitumens possess softening points of 110° to 160°F. and penetrations of 35 to 200 (at 77°F.). In this connection it is interesting to note that flowable compositions having 80 to 85 per cent of the asphalt have been reported.[158] One mode of procedure is first to make an aqueous emulsion containing about 57 per cent bitumen, the average particle size of the latter being about 2 microns. Additional bitumen is then incorporated, mechanical agitation during this latter step being less severe than in the first stage and resulting in the formation of dispersed particles of about 20 to 30 microns in size.

Factors which affect the stability of such emulsions are: presence of some types of electrolytes in the water,[159] hydrogen-ion concentration of the latter, degree of dispersion of the asphalt, and the interfacial tension between the dispersed phase and the aqueous medium. With regard to the hydrogen-ion concentration, Vellinger and Flavigny[160] report that greatest stability (of a 50 per cent asphalt emulsion containing soap as the emulsifying agent) was secured over a *p*H range of 9 to 13. The latter was measured with an antimony electrode. They also point out that the interfacial tension between the dispersed particles and the liquid medium should be as low as possible. Gräfe and Fleck[161] call attention to the undesirability of an extremely fine dispersion since in this manner the total quantity of emulsifier absorbed by the particles is increased. This results in an asphalt film (particularly when the emulsion is applied to road surfaces) which exhibits a tendency to re-emulsify due to the combined action of moisture and traffic.

The interfacial tensions of two asphalts (Fluxes A and B) against aqueous sodium hydroxide, at 85°C., were measured by Traxler and Pittman.[162] The samples employed exhibited the following physical properties:

	Flux A	Flux B
Sp.gr. 85°/85C.	0.9964	0.9970
Float at 150°F., seconds[a]	44	53
Flash (Cleveland Open Cup), °F.	420	415

[a] Time required for water (at a specified temperature) to force a plug of asphalt out of the bottom of a saucer-like aluminum float, thereby causing the latter to sink. For details, see A.S.T.M. Standards, American Society for Testing Materials, Philadelphia, Pa., 1933.

These investigators found that the interfacial tension decreased with increasing concentration of alkali, disappearing when the latter became 0.05 and 0.005 moles per liter for Fluxes A and B, respectively. Some of their results are given in Table 226.

TABLE 226.—*Interfacial Tension between Asphaltic Fluxes and Solutions of Sodium Hydroxide.*

Concentration of NaOH Moles per Liter	Interfacial Tension Flux A Dynes per cm.	Interfacial Tension Flux B Dynes per cm.
0.0000	16.7	15.7
0.0013	11.4	7.9
0.0025	9.5	5.3
0.0050	5.3	0.0[a]
0.0100	0.5	0.0
0.0500	0.0[a]	0.0

[a] Emulsion-formation at the interface apparently occurred with this concentration, and greater, of alkali.

The effect of sodium chloride, in small proportions, was to decrease the interfacial tension of asphalts against aqueous alkali. As the proportion of salt was increased, however, the opposite phenomenon was observed. This is illustrated graphically in Fig. 306 by the data obtained with Flux A and 0.0050 molar sodium hydroxide and Flux B and 0.0025 molar alkali. Substitution of calcium chloride for salt resulted only in increasing the tension.

---

[159] Hard water, for example, before being employed in the preparation of asphalt emulsions, may be softened by treatment with alkali fluorides: K. E. McConnaughay, U. S. P. 1,989,374, Jan. 29, 1935; *Brit. Chem. Abs.* **B**, 1935, 1083.

[160] E. Vellinger and B. Flavigny, *Ann. combustibles liquides*, 1932, 7, 217; *Chem. Abs.*, 1932, **26**, 5473.

[161] F. H. Gräfe and I. R. Fleck, *Petroleum*, 1930, **26**, 357; *Brit. Chem. Abs.* **B**, 1930, 542.

Salts, e.g., sodium borate, carbonate, phosphate or silicate, which yield alkaline aqueous solutions because of hydrolysis, may be employed in place of alkali. With such compounds, however, the concentration required to reduce the interfacial tension to zero varies considerably and is probably dependent not only on the alkalinity of the solution (or degree of hydrolysis) but also on the type of anion present.[163]

Traxler[164] states that the viscosity of aqueous bitumen emulsions is influenced by both the particle size and the particle-size uniformity of the disperse phase, the latter factor being the more important. With a constant phase-volume ratio a decrease in particle size causes a rise in consistency. On the other hand if the particles are not of uniform size there is a decrease in consistency because of the resultant condition of more loose packing with non-uniform than with uniform particles.

FIG. 306.—Effect of Sodium Chloride on Interfacial Tension Between Sodium Hydroxide Solutions and Asphalts. (R. N. Traxler and C. U. Pittman)

PREPARATION OF ASPHALT EMULSIONS

As previously indicated, such emulsions may be prepared by dispersing asphalt (for example, by mechanical agitation) in an aqueous solution of an emulsifying agent. Of the latter the sodium salts of fatty acids are probably the best known and have been widely employed. In some instances these may be used in conjunction with heavy metal soaps. As an illustration, Hepburn[164a] suggests making an emulsion of 9 parts of soap, 78 parts of water and 20 parts of fuel oil. This is mixed with 1 to 2 parts of aluminum oleate and 296 parts of asphalt then dispersed in the composition. In other cases substances which react to form soaps may be employed. Thus, bone fat may be heated with aqueous potassium carbonate and then molten bitumen incorporated.[165] Or stearine pitch (2 to 5 per cent) is dissolved in asphalt and the latter dispersed in a dilute solution of sodium hydroxide.[166]

Alkali rosinates may be substituted for the corresponding fatty acid derivatives.[167] Gabriel and Blott[168] recommend that emulsions prepared with such rosinates be stabilized by incorporation of calcium, or other water-insoluble, salts of rosin. As an illustration, 100 parts of rosin and 3.75 parts of calcium hydroxide are heated at 140°C. until a homogeneous mass is obtained. The latter is dissolved in an equal weight of fuel oil and 4 parts of this solution are added to 100 parts of bitumen. The resulting mixture is dispersed in sufficient aqueous 0.05N potassium rosinate to give an emulsion containing 57 per cent bitumen. Certain esters of abietic or hydroabietic acid have also been recommended, such as those prepared by esterifying in an alkaline medium with a halogeno-aliphatic sulphonic acid or in an acid medium with a hydroxyaliphatic sulphonic acid.[169]

In some instances crude petroleums contain naturally occurring emulsifiers. These may be recovered in the following manner:[170] The crude oil is distilled taking over gasoline, kerosene and the lubricating oil fractions. Alkali, e.g., sodium or potassium hydroxide, is added to the last-named fractions and these are again distilled. In the resulting residue are found the emulsifiers combined with the alkali. The residue may be added directly to the bitumen or it may be treated with an acid (hydrochloric or sulphuric) and the emulsifiers thus liberated be incorporated with the asphaltic material.

As previously mentioned, inorganic alkalies or salts yielding alkaline aqueous solutions may serve as the emulsifying agent. A typical salt is sodium metasilicate.[171] Ernotte[172] suggests the muds resulting from the carbonating of sugar juices as dispersing and peptizing media. Such "carbonating muds" or "sugar scum" are said to contain, in addition to calcium carbonate, colloidal calcium salts such as the pectate. A mixture of slaked lime and alum has also been suggested.[173]

The use of inorganic salts in conjunction with soaps of various types has been recommended, particularly in the preparation of emulsions possessing a high percentage of asphalt. Thus, in preparing a composition containing 1 part of water and 2 parts of asphalt, Steininger[174] uses about 1 per cent of triethanolamine oleate and 1.5 per cent of sodium sulphite or chromate. Sparks[175] employs a small proportion of a mixture of sodium silicate or phosphate and "green acid soap." The latter is derived from the water-soluble sulphonic acids found in acid sludge from the refining of petroleum distillates.[176] In another procedure trisodium phosphate

or caustic alkali serves as the dispersing agent.[177] After emulsification, the composition is incorporated with a small quantity of tannic acid.

Other substances which have been proposed as emulsifying agents are humic acid,[178] rosin soaps,[179] alkali-metal or ammonium salts of oleyl, cetyl or stearyl sulphate,[180] and viscose.[181] Compositions containing humic acid are said to be stabilized by incorporation of a small proportion (0.5 to 1 per cent) of a neutral salt, such as sodium chloride or sulphate or calcium chloride.[182] Taylor[183] uses farinaceous materials, such as corn (maize), gluten or soya-bean meal, mixed with water-soluble soaps of petroleum sulphonic acids (green acid soap). Such an agent furnishes asphalt emulsions which may be diluted with hard water or subjected to wide variations in temperature without breaking. Starchy bodies, such as flour rendered water-soluble by treatment with alkali, incorporated with alkali phenylates or fatty acid soaps, are recommended by Rouault.[184] Before emulsification, the viscosity of the bitumen may be decreased by incorporating phenols (or phenylates) with it.[185]

In addition to emulsifying agents, substances whose functions are to stabilize or prevent the emulsion from breaking rapidly may be included also. To accomplish this Watts[186] suggests employment of an alkali metal caseinate. Afterwards phosphoric or boric acid is added until the *p*H of the composition is 8.5. In addition, a preservative for the casein, such as formaldehyde, may be used. In using sodium caseinate, Bray and Beckwith[187] suggest that the emulsion be prepared and then cooled below 38°C. before incorporating the stabilizer. Sodium phosphate has been recommended as a stabilizer for emulsions prepared with alkali or with soap as emulsifying agent.[188] In the latter case a small percentage of calcium chloride is also incorporated. Thurston[189] points out that spent fuller's earth from the vapor-phase treatment of cracked distillates contains adsorbed saponifiable bodies. Extraction of the latter with acetone or benzene furnishes substances which possess stabilizing properties. Wintsch[190] recommends mixing 5 to 10 per cent rubber latex with a 2 per cent solution of rosin soap which is then emulsified with the bitumen. Water- or alkali-soluble condensation products of formaldehyde and phenols have been proposed also.[191] In other instances the bitumen, prior to emulsification, may be mixed with sulphurized factice, such as obtained by the

action of sulphur chloride on train oil or fatty acids or by heating linseed oil and sulphur to 150-180°C.[192]

Hickman[193] suggested an emulsion made by dispersing bitumen in an alkaline solution of casein to which had been added rosin or a sulphonated fatty oil and a small percentage of acetanilide or salicylic acid. To obtain a stable emulsion of extremely small particle size it is necessary that the alkalinity of the dispersing medium be adjusted so that it is slightly less than the critical point above which a water-in-oil emulsion would be formed.[194]

Use of Clay in Asphalt Emulsions. According to Fain,[195] asphalt emulsions may be classified in two ways: (a) those containing a surface tension depressor, such as soap, and are easily and readily prepared, and (b) those possessing an insoluble dispersing agent such as clay or bentonite. In the latter instance careful regulation of the temperature and viscosity of the dispersing medium during manufacture is necessary. The latter type, however, is generally more stable toward electrolytes and during storage. He proposes to combine both of these effects, stability and ease of preparation, by incorporating both kinds of agents. A typical composition would contain approximately 75 per cent asphalt, 25 per cent water, 0.5 per cent bentonite and 1/16 per cent soap. In some instances the soap may be substituted by a small proportion (0.025 to 0.1 per cent) of a protective colloid. Examples of the latter are gum acacia, agar agar, starch and tannic acid.[196] As a modification, Kirschbraun[197] suggests that an aqueous emulsion containing asphalt (about 70 per cent) and soap be mixed with one (55-60 per cent asphalt) having clay as the stabilizing substance. The resulting product is said to be more fluid than either of the component emulsions. It has been pointed out also that the *p*H value of compositions of which clay is one constituent should be from 6 to 9.[198] For example, steam-refined Mexican asphalt (melting at 120°F.) may be emulsified with an aqueous suspension of bentonite and clay provided the *p*H value of the dispersion is 6.0 to 6.5. On the other hand the optimum emulsive condition for certain pitches (e.g., stearine) exists at a *p*H of about 8.0. Since various clays furnish aqueous suspensions differing greatly in their acidity or alkalinity, incorporation of a small proportion of a modifying agent (such as alum, sulphuric acid, or alkali metal oxides or hydroxides) is often necessary to secure effective dispersion of the asphalt or pitch.

Another procedure comprises emulsifying molten asphalt with 1 to 5 per cent of a concentrated solution of an alkali hydroxide or carbonate and then incorporating an aqueous slurry of clay.[199] The latter material, according to Liberthson,[200] may be employed in small proportions to stabilize bituminous compositions containing petroleum sulphonates as emulsifying agents. Increased fluidity is said to result on the addition of trisodium phosphate to preparations composed of asphalt, clay and aqueous alkali.[201] If soap be used in place of the alkali, then addition of the phosphate should be preceded by that of an alkaline-earth metal salt, such as calcium chloride. Lister[202] recommends an alkaline aqueous suspension of bentonite and sodium or potassium silicate as stabilization agents. Emulsification of bitumen in an aqueous colloidal solution of hydrated magnesium silicate with the aid of 0.1N acetic acid has also been suggested.[203]

USES OF ASPHALT EMULSIONS

The advantages of using emulsions over other methods of applying asphalt coatings have already been pointed out to some extent. Employment of asphalt alone requires heating to a high temperature which may be disadvantageous in some cases. However, asphalt solutions to be brushed or sprayed may introduce fire and health hazards. Among the numerous applications[203a] are in the making of roads, flooring and roofing, in the waterproofing of paper, cloth, wood and concrete and the manufacture of molded material by mixture with various fillers. An important use is in applying protective coating for iron and steel. Treatment of surface soil with bituminous emulsions is said to minimize dust-formation in dry weather and mud in wet weather.[204] A lubricant for bearing surfaces to be subjected to high temperatures consists of an aqueous emulsion of asphalt and graphite.[205]

TESTING OF ASPHALT EMULSIONS

According to Latzko,[206] such emulsions may be divided into three main classes, (a) normally breaking, (b) slowly breaking, and (c) stable. The first-named types, generally containing 45-50 per cent water, are used in road construction, particularly with limestone aggregates, since the bitumen particles are more adherent to this. Stable emulsions are especially applicable for mixing with stone, sand, and other finely-divided material to form an asphalt concrete. Klingmann[207] believes that breaking can be traced mainly to precipitation of the soap in the emulsion by the soluble constituents of the aggregate.[208] However, filtration and evaporation are also factors. As the purpose of bituminous emulsions, in road making, is to envelop the aggregate uniformly with a binding material, any premature breaking will result in irregularities. He suggests as a test that asphalt composition be allowed to flow upwards through a glass tube, packed with aggregate 1 mm. in diameter, and the volume noted which enters the tube before the top surface of the liquid breaks. The latter phenomenon is indicated by a cessation of liquid flow.

Weber[209] proposes covering 10 g. of clean, dried stone (0.6 to 2 mm. diameter) with 50 cc. of the emulsion and allowing the mixture to stand for 1 hour. Afterwards the stone is washed with water to remove excess asphalt, dried, and the increase in weight determined. McKesson[210] describes a breaking test in which 100 g. of the emulsion are stirred with 35 cc. of $0.02N$ calcium chloride. After 2 minutes, precipitated asphalt is filtered, dried at 163°C. and weighed. With slow settling compositions a $0.1N$ solution may be employed.

[209] H. Weber, *Proc. World Petroleum Congr.*, 1933, **2**, 669.

The following procedure[211] has been suggested for estimating the stability of emulsions: 1 g. is placed in a porcelain crucible (1 to 1¼ inch diameter) and concentrated by stirring under an air current at 18-20°C. This is continued until coagulation occurs, generally in ½ to ¾ hour. At this point the residual water content is determined by drying at 110°C. Characteristic values for different types of emulsions are:

Unstable Emulsions (fast)	15-25%	Residual Water
Semi-Stable Emulsions (medium)	8-10%	" "
Stable Emulsions (slow)	5-8%	" "

Another test (Sedimentation test) involves placing 500 cc. of the emulsion in a tall glass cylinder, covered to prevent evaporation, and after 5 days siphoning off the top 450 cc. The remaining 50 cc. plus sediment are then removed and loss on heating ascertained, the final heating period being 3 hours at 325°F. If during standing the sample in the cylinder exhibits creaming, i.e., the sediment floats instead of sinking to the bottom of the container, then the upper 50 cc. are withdrawn and loss on heating determined. The percentage of total solids thus found in the most concentrated layer withdrawn should not differ by more than 3 per cent from that in an equal volume of the initial asphalt emulsion.

One method[212] for measuring particle size comprises diluting 0.1 g. of the emulsion with 30 ml. of sodium oleate solution (1.5 to 2 per cent concentration), adding this to a standard haemacytometer cell, and taking a microphotograph. The number of particles are then counted per square (0.0025 sq. mm.) in the picture. Since the depth of the cell is 0.1 mm., the volume of solution per unit square is 0.00025 cu. mm. or 0.00025×10^{-3} cc. The mean radius (r) of the particles may then be calculated according to the formula

$$r = \sqrt[3]{\frac{3}{4\pi d} \times \frac{WB}{30} \times 0.00025 \times 10^{-3} \times \frac{n}{N}}$$

in which W is the weight of emulsion, B is the bitumen content and d its density, N is the total number of particles counted, and n the number of squares in which they appear.

Other inspections which are often made include total bitumen content, viscosity (usually Engler), resistance to low temperatures, homogeneity or screen test, i.e., proportion of asphalt held back when the emulsion is poured through a 20-mesh screen, water content, and stability to dilution with water.[213]

Methods outlined by the American Society for Testing Materials[214] for testing asphalt emulsions include measurement of viscosity, residue on distillation, percentage of water, miscibility with water, settling on standing, demulsibility, freezing test, residue on sieving, and coating test on stones. Percentage of water is determined by mixing the emulsion with an equal volume of a light oil or coal-tar naphtha (b.p. 120-250°C.) and distilling. Demulsibility is measured by adding to 100 g. of emulsion 35 cc. of 0.02*N* (for quick-setting type) or 50 cc. of 0.1*N* calcium chloride (for mixing type of emulsion) with continuous stirring and then weighing the precipitated asphalt which is caught on a No. 14 standard sieve.

Much the same types of tests are suggested by the British Standards Institution[215] with some exceptions. For example, in determining the percentage of water, the diluent employed has a narrower boiling range (125-160°C.) than that given above. Also, the rate of breaking of emulsions is measured by the "lability test," the assumption being made that the cause of breaking is the evaporation of water. A small portion of emulsion is placed in a porcelain crucible and stirred gently with a specially designed glass rod while a current of air at 18-20°C. is blown carefully over the surface. The time is recorded for coagulation to take place as determined by the collection of coagulum on the stirring rod.

Chapter 52

Reduction of Carbon Monoxide to Hydrocarbons. The Kogasin Synthesis and Synthetic Petroleum

Because of the wide variety of substances that may be produced by the catalytic hydrogenation of carbon monoxide, considerable interest has been manifested (especially abroad) in this type of synthesis. There are primarily two distinct types of operation, one of which leads to the formation of oxygenated compounds, and the other to hydrocarbons. Differentiation between the two processes is that the first requires high pressure treatment whereas the second is carried out at substantially atmospheric conditions.

Since about 1923, the high-pressure method has been exploited commercially in the production of methanol, or synthetic wood alcohol. In the same year, Fischer and Tropsch[1] found that by using a catalyst of iron and potassium carbonate a mixture of higher alcohols and other oxygenated substances (the so-called "Synthol") could be obtained from carbon monoxide and hydrogen by similar treatment. Normal alcohols up to nonanol ($C_9H_{19}OH$), fatty acids ranging from formic up to octanoic ($C_7H_{15}COOH$) and numerous aldehydes, ketones and esters, together with small quantities of hydrocarbons, were isolated from the reaction product. On the other hand, when low pressures are involved, methane is the resultant, as was shown by Sabatier and Senderens[2] in 1902. Later (1918), Orlov[3] synthesized ethylene by reducing carbon monoxide in the presence of coke impregnated with nickel and palladium. However, in 1926, Fischer and Tropsch[4] reported that with iron, nickel and cobalt catalysts and with treatment at atmospheric pressure it was possible to produce a mixture of the higher hydrocarbons (the so-called "Synthin" or "Kogasin"), similar to petroleum hydrocarbons.[5]

This chapter will be devoted expressly to a discussion of the second method of treatment, that involving the use of ordinary pressure, because of the relation of its products to those of the petroleum industry. Numerous preliminary investigations, conducted both in Germany and in Japan, had indicated that certain of the Synthin fractions may have possible application as motor or Diesel fuels, and that heavier-molecular weight portions could be cracked to furnish additional yields of gasoline. As a matter of fact, Fischer[6] states that by 1934 pilot plant and semi-works scale apparatus were developed to such an extent in Germany that it was decided to build a large commercial unit. Construction along this line was undertaken at that time, and Fischer believed that in a short while the carbon monoxide-hydrogen synthesis would become an important factor in fulfilling the fuel requirements of Germany by creating what may be termed a "synthetic petroleum" industry.

Special names have been given to the fractions obtained in the Synthin treatment. The lower boiling hydrocarbons (containing 2 to 5 carbon atoms per molecule), which are gases at ordinary temperatures, are called "Gasol." The oily portion is referred to as "Kogasin" and consists of a mixture of straight- or slightly branched-chain saturated and unsaturated hydrocarbons. The part of the oil boiling in the gasoline range (30° to 200°C.) is known[7] as Kogasin I and the high-boiling residue (over 200°C.) as Kogasin II. Two types of solid paraffin waxes are formed, one (that separated from Kogasin by cooling) melting at about 40°C. and the other at about 96°C. The latter substance is termed synthetic "Ceresin" because of its similarity to naturally occurring wax of the same name.[7a] The expression "Synthin" is but little used at present, because of the fact that at one time it was applied to the mixture of hydrocarbons obtained by reduction of the oxygenated compounds produced in the Synthol treatment. The reaction is now commonly known as the Kogasin or Fischer-Tropsch synthesis, the first specifically pertaining to oils prepared from water gas[8] and the second a more or less general term.[9]

MECHANISM

Fischer and Tropsch[10] have proposed a mechanism for the synthesis of the higher hydrocarbons from carbon monoxide and hydrogen based on the formation of intermediate metallic carbides. Thus, in the presence of catalysts such as finely divided nickel, cobalt or iron, carbon monoxide is thought to be reduced to elemental carbon, which unites with the finely divided metals to form carbides. The latter apparently are not the ordinary low carbon content substances which are stable at high temperatures, but are quite rich in carbon, and are stable only at relatively low temperatures. They are reduced by hydrogen to form methylene radicals (CH_2), which in turn polymerize. Fischer and Tropsch are of the opinion that this theory explains the removal of carbon (from the carbides) as higher hydrocarbons rather than as methane. Fischer and Koch[11] have suggested the existence of methyl (CH_3) and methinyl (CH) radicals in addition to methylene, which might give rise to some of the substances noted in the reaction mixture.

Two distinct types of interaction have been observed by Fischer[12] using different catalysts. With nickel and cobalt, for instance, at 200°C. the mechanism may be represented as:

---

[7] The term "Kogasin" is a contraction of the German: Kohle-Gas-Benzine.

[12] F. Fischer, *loc. cit.*

$$CO + 2H_2 + Co_3C \longrightarrow Co_3C_2 + H_2O + H_2 \longrightarrow Co_3C + H_2O + (CH_2)$$

Under these conditions carbon monoxide is reduced to water and a higher metallic carbide (indicated by Co_3C_2). The latter is decomposed in a second step, giving rise to hydrocarbons by polymerization of the methylene radicals. On the other hand, iron behaves in quite a different manner. Fischer has suggested the following reaction with this catalyst at 250°C.:

$$2CO + H_2 + Fe_3C \longrightarrow Fe_3C_2 + CO_2 + H_2 \longrightarrow Fe_3C + CO_2 + (CH_2)$$

The difference between these two equations is that nickel and cobalt favor the union of 2 molecules of hydrogen and 1 of carbon monoxide, resulting in the formation of water, whereas with iron, 2 molecules of carbon monoxide and 1 of hydrogen unite and produce carbon dioxide as the by-product.[13]

THERMODYNAMIC CONSIDERATIONS

The application of thermodynamic principles to the Fischer-Tropsch process leads to several interesting conclusions.[14] Using the mechanism proposed by these investigators and the approximate linear free energy-temperature relation derived by Parks and Huffman[15] for carbon monoxide, water, methane, ethane, benzene, cyclohexane, *n*-hexane, *n*-hexene and *n*-octane, the following over-all equations may be obtained for reactions occurring in the gas phase with nickel or cobalt catalysts:

(1) $CO + 3H_2 = CH_4 + H_2O_{(g)}$; $\Delta F^\circ = -51{,}300 + 56.2T$
(2) $2CO + 5H_2 = C_2H_6 + 2H_2O_{(g)}$; $\Delta F^\circ = -90{,}400 + 117.4T$
(3) $6CO + 9H_2 = C_6H_{6(g)} + 6H_2O_{(g)}$; $\Delta F^\circ = -173{,}200 + 240.9T$
(4) $6CO + 12H_2 = \text{cyclo-}C_6H_{12(g)} + 6H_2O_{(g)}$; $\Delta F^\circ = -224{,}700 + 335.6T$
(5) $6CO + 12H_2 = n\text{-}C_6H_{12(g)} + 6H_2O_{(g)}$; $\Delta F^\circ = -211{,}400 + 316.3T$
(6) $6CO + 13H_2 = n\text{-}C_6H_{14(g)} + 6H_2O_{(g)}$; $\Delta F^\circ = -241{,}300 + 350.2T$
(7) $8CO + 17H_2 = n\text{-}C_8H_{18(g)} + 8H_2O_{(g)}$; $\Delta F^\circ = -317{,}500 + 466.6T$

These equations are represented graphically in Fig. 307, together with the temperature limits for the Kogasin (hydrocarbon) and for the Synthol (alcohol) syntheses (represented by the solid vertical lines) and the optimum temperatures (indicated by the dotted vertical lines) for the various catalysts in common use.

Considering first the Kogasin range, it will be seen that the production of hydrocarbons from carbon monoxide and hydrogen is favored thermodynamically, as is evidenced by the large negative values of the standard free energy change (ΔF°) for the over-all reactions. In the series methane, ethane, *n*-hexane and *n*-octane, ΔF° becomes more negative with the size of the molecule, so that the formation of higher members of the series might be expected to be quite feasible. From his thermodynamic calculations, Smith[15a] stated that at about 300°C. and atmospheric pressure, it should be possible to obtain any of the paraffin hydrocarbons by reduction of carbon monoxide in the presence of appropriate catalysts. The validity of this conclusion has since been confirmed by the isolation and identification of some of the reaction products,[16] which included practically all the members of the aliphatic series from ethane to hectopentacontane ($C_{150}H_{302}$).

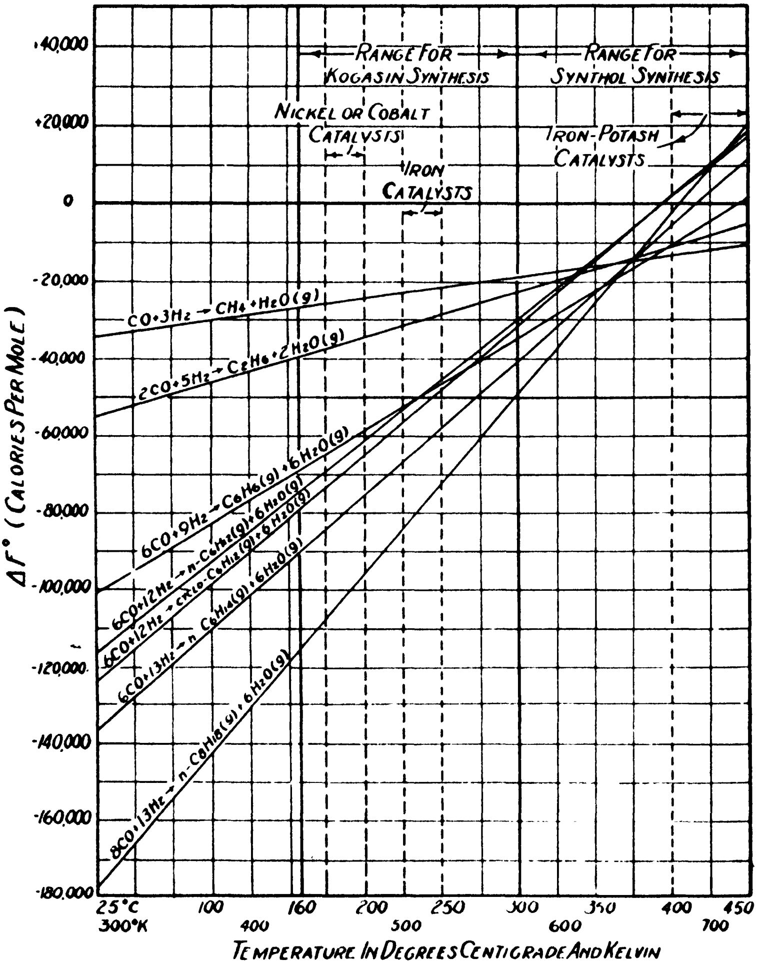

FIG. 307.—Molar Free Energy-Temperature Relationships in Reactions Yielding Hydrocarbons from Carbon Monoxide and Hydrogen.

Curves for the 4 six-carbon compounds, *n*-hexane, cyclohexane, *n*-hexene and benzene show that there is a slight thermodynamic favorability for the former rather than the cyclic, olefinic or other benzenoid types. The ΔF° for *n*-hexene is about 15,000 to 10,000 cal. less than that for *n*-hexane over this temperature range, so that the proportion of unsaturates in the reaction mixture may be predicted to be less than that of the corresponding saturated hydrocarbons. This is also in agreement with experimental observations, since the paraffinic type ordinarily predominate. (Nevertheless, the olefinic content may be increased by variations in the operating conditions, as will be discussed shortly.) From a thermodynamic viewpoint, cyclohexane and benzene (C_6H_6) might also be expected to be among the reaction products. However, as yet, reports as to the presence of the cyclic paraffin have only been negative, and the latter aromatic hydrocarbon is found only in traces.[17] Smith[18] believes that with the proper choice of a catalyst, the latter reaction could be made to go into effect.

---

[16] See the section of this chapter devoted to the Chemical Composition of Products.

All of the free energy curves exhibit a decided positive slope, i.e., ΔF° assumes a more positive value (or the driving force of the reaction lessens) with increasing temperatures. At those employed in the Synthol reactions (about 300-450°C.) for the formation of oxygenated compounds, the free energy functions for all the higher hydrocarbons fall to relatively small negative or positive values. Ethane, and especially methane have smaller slopes than other hydrocarbons and consequently their formation is more highly favored than the higher members. At temperatures above 375°C., methane should be one of the principal resultants in the reduction. This, too, is borne out by experimental data.

The second mechanism proposed by Fischer[19] to account for the by-product carbon dioxide in the reaction mixture when iron catalysts are employed may be subjected to similar thermodynamic consideration. In this respect, the calculations of Smith[20] show that there is a somewhat greater tendency for the oxygen to form carbon dioxide rather than water. This means that there exists a greater driving force for the second type of reaction (that with iron contact agents). Consequently, it may be predicted that slightly higher temperatures can be used with iron catalysts, which is also in agreement with experimental facts.

THE INFLUENCE OF VARIOUS FACTORS IN THE KOGASIN SYNTHESIS

The influence of the numerous factors involved in the synthesis of hydrocarbons by the catalytic reduction of carbon monoxide has been summed up by Friedwald[21] as:

1. Increase of pressure → Synthol (methanol and higher alcohols and other oxygenated compounds
2. Increase in hydrogen content → methane
3. Decrease in hydrogen content → olefinic hydrocarbons
4. Increase of temperature → methane and finally carbon
5. Catalysts increase the degree of saturation of the product in the order iron, cobalt and nickel
6. Presence of carbon dioxide is without influence
7. Increase of life of catalyst gives an increase of light fraction and a decrease in oil content.

These points will be considered in due course in this chapter. It should be borne in mind, however, that the above-mentioned variations are only generalities and need further elaboration. But before so doing, it is advisable to discuss the catalysts and methods of their preparation.

CATALYSTS

These play an extremely important part in the carbon monoxide-hydrogen synthesis and must have hydrogenating power even at very low temperatures. However, this latter property should not be too pronounced as saturation of methylene radicals occurs, thus giving rise to methane and inhibiting polymerization (of methylene) to higher homologues. Fischer and Tropsch[22] reported that the metals of the eighth group of the periodic table were applicable for the production of liquid hydrocarbons. Of these, finely divided cobalt was stated to be the best, with iron somewhat slower in its action, and nickel quite weak in its ability to form hydrocarbons other than methane. Fujimura and Tsuneoka[23] disagree with this observation and assert that in the range of 190 to 200°C., pure nickel gives better yields of liquid than cobalt. However, the contact agents in most general use are seldom the pure metallic elements themselves, as it has been observed that their effectiveness is greatly enhanced by the addition of various promoters. Furthermore, the manner of preparation also exerts an enormous influence not only on the yield of products but also on the life of the catalyst. Each of these factors will now be discussed briefly.[24]

Fischer and Tropsch[25] recommended mixing 1 to 3 parts of other substances, such as the oxides of chromium, zinc, beryllium and rare earth metals, and metals such as uranium, silicon, magnesium and manganese and activated carbon, to the above mentioned finely divided metals of the eighth group. According to Fujimura and Tsuneoka[26] the activity of nickel-thorium dioxide catalysts (containing 18 per cent ThO_2) is greatest at 195°C., and can be markedly increased by the addition of small amounts of potassium carbonate or rubidium carbonate. Nickel-manganese compositions are said to be adversely affected by sodium or potassium carbonate, but are improved by rubidium carbonate. Chromium and uranium may also be added. Subsequent investigations by these workers[27] using oxides of chromium, molybdenum, tungsten and uranium with nickel-manganese catalysts show that the promoting influence increases with the atomic weight of the metal. Of the numerous mixtures employed, the maximal results were obtained with thoria, alumina and fuller's earth as accelerators. Nickel-manganese-copper (15 per cent Mn and 0.5 per cent Cu) contact material was also reported to be an effective combination. The activity of mixtures of nickel and thoria, nickel and alumina and nickel and barium oxide (each containing 90 per cent Ni and 10 per cent promoter) and nickel-silica (80 per cent Ni, 20 per cent SiO_2) were studied by Muszkat.[28] His results indicate that, over periods of 50 hours usage, the first three pairs are practically unaffected, but the latter (Ni-SiO_2) lost 80 per cent of its catalytic ability during the operations. However, the presence of oxygen in the reaction mixture instantly inactivated all of these. Klyukvin and Vol'nov[29] noted that nickel-thorium, nickel-thorium-mercury and nickel-magnesium masses were satisfactory for the production of gasoline, giving optimum conversions of 100 g. per cubic meter of gas, or 30 to 40 per cent. On the other hand, Tsutsumi[30] reported a yield of 168 g. of total liquids from 1 cubic meter of gas using a nickel catalyst to which was added 20 per cent of manganese, 8 per cent of uranous-uranic oxide (U_3O_8) and 4 per cent of thorium oxide.

Fischer and Koch[31] obtained up to 153 cc. of liquid hydrocarbons per cubic meter of gas mixture, or 71 per cent of the theoretical, with catalysts of cobalt and 18 per cent thorium or 15 per cent manganese. These were imbedded on kieselguhr carriers. Fujimura[32] used a mixture of 8 parts of cobalt, 1 part of copper, 0.15 part of thorium, 0.15 part of uranium and 9.3 parts of starch, also carried on kieselguhr. Silver is said to be superior to copper as a promoter for cobalt, according to Tsutsumi.[33]

Gillet[34] investigated the relation between yield and catalyst and holds that iron with additions of nickel, manganese, aluminum, thorium or cobalt, either singly or together, is the most effective type of contact agent. In this connection it is of interest to note that Fischer and Meyer[35] reported that incorporation of iron with mixed nickel-cobalt catalysts decreases their activity. Ghosh and Sen[36] studied the effects of iron-copper combinations containing nickel, cerium and thorium. The maximum conversion to liquids that they obtained (43.4 per cent) was with a mixture composed of 4 parts of iron, 1 of copper, 0.25 of nickel, 0.0041 of cerium and 0.0296 of thorium. Braune[37] advocated the addition of small quantities of halides of alkaline earth metals to iron, as for instance, calcium chloride to magnetic iron oxide (Fe_3O_4). The inclusion of small quantities (0.005 mole) of sodium carbonate in equimolar mixtures of copper-iron catalysts is also said to increase the productivity of the mass.[38] Lefebvre and Le Clerc[38a] report that an iron oxide corresponding to magnetite causes mainly the formation of gasoline hydrocarbons from carbon monoxide and hydrogen. However, the presence of potassium (presumably as $KFeO_2$) in the catalyst caused heavy aliphatic hydrocarbons to be produced also.

Fujimura[39] has stated that the physical condition of the catalyst is just as important as its chemical composition. Both the manner of preparation and also the reaction temperature are of significance in determining the life of the contact mass.[40]

Fischer[41] has compiled a list of 9 catalysts (See Table 227) together with their method of formation in order to show their relation to the yield of liquid products and the life of the catalyst (i.e., the time required for the catalyst to lose 80 per cent of its initial activity, as indicated by the conversion of the gases to liquids). In the case of cobalt-thorium-kieselguhr it will be noted that the precipitated contact mass gives a slightly higher yield of liquid products and has more than twice the life of an analogous material obtained by decomposition methods (such as by thermal treatment, as will be discussed shortly). Those compositions containing iron have a relatively short span of activity and also furnish relatively low yields of liquid, according to these data of Fischer. Tsutsumi[42] found that by using an excess of hydrogen over the ratio: $CO:H_2 = 1:2$, both the life of the contact mass and the quantity of gasoline may be increased.

TABLE 227.—*Yield of Liquid Products and Duration of Activity of Some Catalysts for the Carbon Monoxide-Hydrogen Synthesis from Water Gas.*

	Method of Preparation	Yield of Liquid g. per cubic meter of water gas	Duration of Time for 80% Loss of Initial Activity, days
Fe-Cu-Mn-silica gel –0.4% K_2CO_3..	decomposed	about 30-35	8
Fe-Cu-kieselguhr................	precipitated	" 28	8

Co-Ni-Si........................	skeleton	85	12
Co-Th-Cu-kieselguhr.............	precipitated	105	60

Preparation of Catalysts. One of the most common procedures is that recommended by Fischer.[43] According to this method, kieselguhr is suspended in water and solutions of nickel nitrate and thorium nitrate are added. The metals are precipitated as hydroxides (with sodium hydroxide), the insoluble substances filtered, washed free from occluded salts and dried. The product must be activated by reduction, which is accomplished by heating in a stream of hydrogen at 350°C. Aicher, Myddleton and Walker[44] prefer to modify this treatment in the case of nickel-magnesium-aluminum-kieselguhr catalysts. The metal nitrates (in solution) are mixed with the kieselguhr, and then precipitated with potassium carbonate. The resulting magma is boiled for about 15 minutes, filtered by suction and washed with hot water. The filter cake is dried, crumbled and moistened with a solution of ethyl orthosilicate in toluene. The moist powder is then pressed into rods about ¼ inch in diameter, which are exposed to moist air for 2 days and subsequently broken into pellets of the desired size. After several more days exposure, the granules are ready for reduction. The latter step is accomplished in the catalytic chamber by passing in hydrogen at 450-480°C. for several hours.

As an example of thermally decomposed catalysts, the method of Fujimura and Tsuneoka[45] may be cited. These workers make a composition, consisting of 8 parts of cobalt, 1 of copper, 0.2 of thorium and 0.1 of uranium, by adding starch to a solution of the nitrates of these metals, evaporating to dryness and calcining. The starch serves a dual purpose in this instance, furnishing carbon to reduce the oxides to the corresponding metals and at the same time effecting a desirable porosity of the mass. This catalyst is said to give a yield of gasoline of 145 cc. per cubic meter of gaseous reactants at 210°C. with one passage. Irradiation of the contact mass with 50,000 volt X-rays had no marked influence on its activity.

Antheaume[46] has suggested adding sodium hydroxide to an equimolar solution of iron and copper nitrates and leaching the precipitate with water until the washings are faintly alkaline ($p\text{H} = 7.4$). About 2 per cent of potassium carbonate is added and the mass granulated, dried and reduced with hydrogen at 250°C. Catalysts prepared by precipitation with ammonia in place of sodium hydroxide generally show poor activity, but can be improved somewhat in this respect by omitting the potassium carbonate. X-Ray studies revealed that these iron catalysts consist of two iron oxides, ferric (Fe_2O_3) and magnetic (Fe_3O_4), but not free iron. The magnetic oxide was thought to be present in the form of solid solution. According to Lefebvre and Le Clerc[46a] thermomagnetic analysis indicated magnetite in a catalyst prepared by precipitation of ferric hydroxide from ferric nitrate solution with ammonia or sodium hydroxide and subsequent reduction with hydrogen. Addition of 1 per cent of potassium carbonate in the initial stage of this procedure gave a catalyst which contained, according to thermomagnetic analysis, a solid solution of potassium ferrite ($KFeO_2$) in cubic ferric oxide (Fe_2O_3).

Antheaume[47] believed that copper performs 3 functions in contact mass: it activates the catalyst, permits low-temperature reduction of the metallic oxides and acts as a stabilizer. Fischer and Meyer[47a] tried to lower the reduction temperature (450°C.) of nickel-manganese-aluminum mass by the addition of copper, but were unsuccessful. They also noted that simultaneous precipitation of copper with the other metals lowered the reactivity of the product. However, when copper oxide or carbonate was added to the precipitated catalyst, it exerted a promoting effect.

Alloy Skeleton Catalyst. Fischer and Meyer[48] have pointed out that there are many disadvantages to the use of certain highly active precipitated catalysts. In the first place, many of the contact agents of this type are too voluminous, and thus occupy too much space. Furthermore the heat conductivity is so poor that there is great danger of local overheating with consequent increased formation of gases in place of liquid products. Grinding and the application of hydraulic pressure have been suggested as methods of reducing the volume-weight ratio of some contact materials.

However, the Raney[49] method has been found satisfactory for producing so-called "alloy-skeleton" catalysts, which Fischer and Meyer report to be quite effective, incorporating a large surface into a small volume and enhancing the heat conductivity. In this method, metallic nickel is alloyed with aluminum or silicon, and the latter elements subsequently removed by dissolving in sodium hydroxide. Thus, nickel and aluminum are fused in a high frequency electric furnace. After cooling, the alloy is broken into pieces about the size of a pea, and heated in boiling water under a reflux condenser. A slight excess of sodium hydroxide (25 per cent solution) over that theoretically required to combine with the aluminum is added gradually over a period of about 6 hours. The clear solution of sodium aluminate is poured off and the nickel is washed 6 times with hot water. Silicon cannot be removed as readily as aluminum, and even after 18 to 20 hours' heating about 5 to 10 per cent of silicon remains in the contact mass, according to these workers. The finished catalyst is kept under water to prevent oxidation. The resulting nickel skeleton is activated by treatment with hydrogen at 350°C. Subsequent impregnation of the skeleton with thorium nitrate is said to have a promoting effect. Cobalt and cobalt-nickel catalysts may be made in a similar manner. Fischer and Meyer obtained yields up to 130 cc. of liquid products per cubic meter of gas (23 per cent of carbon monoxide and 46 per cent hydrogen) and with a feed stock having a high-content of reactants (containing 31.7 per cent carbon monoxide and 65 per cent hydrogen), conversions as high as 161 cc. per cubic meter were secured. These results were confirmed by Tsuneoka and Murata.[50] These investigators advocate a somewhat longer period of heating (24 hours) to effect the removal of silicon from the alloy and also elimination of the last traces of sodium hydroxide remaining in the pores of the mass by extraction with ethyl alcohol.

According to Tsuneoka and Murata[51] pretreatment of nickel-cobalt-silicon alloy catalysts with hydrogen is unnecessary, as no increase in activity can be obtained by reduction at 220°C. At 350° to 450°C. such treatment is said to be detrimental, and at the latter temperature completely deactivates the catalyst. Oxidation of the mass before or after the reduction is likewise thought to be unfavorable. These investigators also noted that the activity of the alloy skeleton decreased greatly with increasing particle size, except with cobalt skeletons. In the latter, a marked decrease in such grain size gives a loss in activity.[52] Manganese acts as a poison to the nickel-cobalt-silicon alloys, checking hydrogenation and accelerating polymerization. From a study of the relation between the gas contraction and the temperature used in reducing the catalyst, Watanabe, Morikawa and Igawa[53] concluded that greater activity is associated with lower temperature values.

PRESSURE

The effect of pressure on the carbon monoxide-hydrogen interaction has been demonstrated by Fischer and Küster.[54] They used an electrically heated horizontal cylindrical rotating autoclave of 3 liters capacity and a catalyst (200 g.) of the cobalt-thorium-copper-cerium-kieselguhr type (9 parts of Co, 2 of Th, 1 of Cu and 0.25 of Ce) suspended in 1 liter of paraffin oil.[55] The feed gas (consisting approximately of 28 per cent of carbon monoxide and 59 per cent of hydrogen) was kept in intimate contact with the suspended catalyst by rotation of the autoclave (100 r.p.m.). Table 228 summarizes the results of tests made at 250°C. and 1, 10, 30 and 50 atmospheres pressure.

From these data it will be noted that hydrocarbon production decreases greatly as the pressure is increased. The quantity of gasoline reached a maximum (33.0 cc. per cubic meter of gas) at atmospheric pressure. However, at higher pressures, the proportions of lower boiling liquid hydrocarbons is much greater, although the

[55] The reason for carrying out the reaction in the liquid phase rather than in the gaseous phase was to prevent spots of local overheating on the catalyst.

amount of total liquids decreases greatly. With increase of pressure the Kogasin process shows a distinct trend, encroaching more and more into the region of Synthol formation, in that alcohols, acids and other oxygenated compounds result.

Thus, Fischer and Küster believe that by means of proper control of the pressure, both Kogasin and Synthol can be produced simultaneously with a cobalt catalyst. Their experimental work indicates that for the generation of hydrocarbons, the pressure should be about one atmosphere.

TEMPERATURE

Fischer and Küster[56] also studied the effect of temperature on the carbon-monoxide-hydrogen reaction using the catalyst and apparatus just previously described. By carrying out the reactions in the liquid phase (i.e., by suspending the catalyst in oil) it was possible to control and also measure the temperature of the reaction much more closely. Thus, when the catalytic reduction of carbon monoxide takes place in the gas phase, it is more than likely that "active spots" on the solid catalyst have a much higher temperature than the average value as indicated by a thermometer. However, in the oil phase, a more equal distribution of temperature results, and therefore these investigators used a slightly higher average reaction temperature to compensate for this effect. Table 229 summarizes their data, obtained in experiments at 30 atmospheres pressure and temperatures of 200°, 210°, 220° and 250°C.

The yield of total liquid product is quite low, and under the pressure employed, the percentage of alcohols formed is appreciable. However, at 250°C. it will be noted that the proportion of gasoline is the highest, being almost 50 per cent of the total liquids. Likewise considerable amounts of lower hydrocarbons, such as methane and ethane, become evident at this temperature.

Control of Temperature and Design of Catalyst Chambers. According to Fischer[57] the optimum temperature for both cobalt and nickel catalysts at atmospheric pressure is approximately 180° to 200°C., and for iron, 230° to 250°C.

However, due to the fact that a considerable quantity of heat is liberated (with complete conversion, amounting to about 20 per cent of the heat of combustion of the feed gas) unless some control is exercised, the reaction temperature would rise several hundred degrees. This would result in the formation of methane and lower gaseous hydrocarbons, and finally carbon, in place of the desired liquids. The difficulty has been overcome by employing specially designed catalyst chambers from which the heat may be rapidly conducted away, by means of oil circulation or radiation.[57a].

A type of apparatus used for semi-commercial operations employs a nickel-manganese-alumina catalyst packed into narrow rectangular metal units about 2x20 cm. in cross-section and 5 m. long.[58] The cases are immersed in a thermostat of circulating oil. With chambers of this design, the temperature control was automatic, and no great difficulty was said to be experienced in maintaining the reaction temperature between 190° and 210°C. Audibert[59] has discussed a similar unit used by Fischer for pilot-plant operation. Thin flat rectangular cases having a volume of about 70 liters are made by welding iron sheets 5x1.2 m. in dimensions to tubes of about 15 mm. diameter. About 21.3 kilograms of catalyst are packed into the frame, which is also surrounded by oil. Units of these dimensions treat about 6.8 cubic meters of gas per hour and cannot furnish more than 12 kilograms of liquid per day (7 to 8 grams per liter of catalyst volume).

Aicher, Myddleton and Walker[60] state that the most favorable yields of gasoline are obtained when the temperature is controlled to within ±5°C. The condition places a sharp limit upon the distance between the center of any catalyst layer and the conducting walls of the reaction chamber. These investigators advocate for laboratory-scale experiments, tubes of 15 mm. diameter, set into an aluminum frame. The latter should be provided with electrical resistance coils for the initial heating and also a jacket for circulation of a cooling medium to carry off the excess heat of reaction.

EFFECT OF VARIATIONS IN THE COMPOSITION OF THE FEED GAS

The theoretical composition of the feed gas should be 1 volume of carbon monoxide to 2 of hydrogen, which represents the stoichiometric quantities required for maximum yield of liquids. However, industrial gases always contain these components in varying proportions and admixed with others, e.g., nitrogen. The effect of such variations will be discussed in this section.

Tsuneoka and Fujimura[61] studied the influence of varying the composition of mixtures of pure carbon monoxide and hydrogen using a nickel-manganese-thoria-kieselguhr catalyst. They concluded that an excess of carbon monoxide has no deleterious effect on the yield of liquids, but that an excess of hydrogen favors the formation of methane. From observations with ratios of carbon monoxide to hydrogen of 1 :1, 1 :1.35, 1 :2 and 1 :3, these workers averred that the optimum composition should lie between 1 :2 and 1 :2.1 for the production of liquids. This is in accordance with the theoretical considerations, assuming the average hydrocarbon formed to be nonane:

$$9CO + 19H_2 \longrightarrow C_9H_{20} + 9H_2O$$

Watanabe, Morikawa and Igawa[62] also experimented with mixtures of gas in approximately the same range (1 :0.97 to 1 :2.96). They do not wholly agree with the conclusion of Tsuneoka and Fujimura regarding an excess of carbon monoxide, and report that when this component is present in concentrations greater than that called for theoretically, the generation of gaseous olefins and carbon dioxide and also liquid products is accelerated while that of the gaseous paraffins is reduced. It was also pointed out that dilution of the feed gas with nitrogen and carbon dioxide favored production of carbon dioxide and gaseous olefins, but this time at the expense of the liquid product. This was attributed to the lowering of the partial pressure of carbon monoxide.

However, Fujimura and Tsuneoka[63] report that only large quantities of diluents exert an appreciable effect on the yield of liquid hydrocarbons. Using a feed stock consisting of 32.8 per cent carbon monoxide, 65 per cent hydrogen and 2.2 per cent nitrogen and a nickel-manganese-thoria-kieselguhr contact agent, 117 cc. of gasoline per cubic meter of gas (corrected for volume of inert constituents) was obtained. The above stock then was diluted with either methane, carbon dioxide or nitrogen, in approximately 10, 20 and 40 per cent concentrations, and treated under the same conditions. The yields of liquid boiling in the motor fuel range (calculated on the basis of active gas passed) from these tests are incorporated in Table 230.

TABLE 230.—*Effect of Dilution of Gaseous Feed Stock on Yield of Gasoline. Feed Stock: 32.8% CO, 65% H_2, 2.2% N_2*

Diluent	Yield in cc./cubic meter active gas		
	10%	20%	40%
Nitrogen	115	112	95
Methane	120	106	85
Carbon dioxide	111	91	90

Fujimura and Tsuneoka concluded that addition of less than 20 per cent of inert gas did not seriously affect the reaction, but that 40 per cent lowered the conversion to boiling liquids. They also noted that the greater the dilution, the lighter and more volatile became the oil produced.[64]

Rapoport, Blyudov, Shevyakova and Frantzuz[65] suggest addition of small proportions of ammonia to the reacting gas to increase the yield of gasoline. This is said to be particularly effective with catalysts precipitated on fuller's earth.

In general, the effect of sulphur is to deactivate the catalyst, and therefore this element should be removed in operations involving commercial gases. (This matter will be discussed subsequently in this chapter.) Yet special investigations as to the action of hydrogen sulphide or carbon disulphide on nickel catalysts, indicate that small quantities of either of the two sulphur compounds actually increased the activity of a nickel-manganese-alumina (15 per cent Mn, 3 per cent Al_2O_3) catalyst but had no effect on a nickel-manganese-thoria mass, (15 per cent Mn, 3 per cent ThO_2).[66] Large amounts poisoned both catalysts, the latter being more readily susceptible. To diminish the activity of the first-mentioned contact agent to 50 per cent of its original value required 54 mg. of hydrogen sulphide per gram of nickel, whereas this same reduction for the other mass was secured with only 16 to 28 mg. of hydrogen sulphide or approximately 50 mg. of carbon disulphide per gram of nickel. The poisoning power of the latter substance was determined to be directly proportional to its concentration. That of hydrogen sulphide, however, varied with the logarithm of its concentration. On the basis that the deleterious alteration is due to the development of nickel sulphide, these workers calculate that only 3.5 per cent of the total nickel in the contact mass is active in forming higher hydrocarbons.

TIME OF CONTACT

Unfortunately there is no manner in which the time of contact can be evaluated in the synthesis. This is due to the fact that the gas undergoes a large contraction in volume and at the same time loses considerable velocity in passing through the layers of catalyst. However, the influence of the feed-gas velocity has been studied by Fischer and Küster[67] using the oil-suspended cobalt-thorium-copper-cerium catalyst mentioned previously. Experiments were carried out under operating conditions of 250°C. and 10 or 30 atmospheres pressure with constant outlet velocity of 20 liters per hour. The results of these investigators are given in Table 231. The data indicate that under the pressures used, formation of hydrocarbons is favored by relatively fast input-gas velocities, whereas slower rates (or longer periods of contact) induce the production of alcohols. In the test conducted at 30 atmospheres pressure and feed-gas velocity of 40 liters per hour, the increase in the proportions of methane and carbon dioxide is worthy of note.

However, Watanabe, Morikawa and Igawa,[68] using a cobalt-copper-thoria composite at 197°C. and atmospheric pressure, found that the yields of gasoline and water per liter of gas ($CO:H_2=33.1:64.7$) decreased with increasing gas velocity. They concluded that the optimum rate for production of gasoline was 1.1 liters per

hour per gram of cobalt. At higher speeds, the conversion drops off, which these workers attribute as possibly being due to the time required for diffusion of the gases through the layer of products surrounding the catalyst. That the reaction, as well as its extent, is influenced by increasing the gas velocity is shown by the correspondingly increased yield of gaseous olefins and also the density of the condensate. The rate of input feed recommended by Fischer, Roelen and Feisst[69] for the most economical yields of gasoline is 75.5 liters per hour per liter of catalyst space.

Aicher, Myddleton and Walker[70] have derived an expression for estimating a "time factor" (for contact materials packed in tubes) which is approximately proportional to the actual time of contact. This quantity was obtained by plotting the relation between the flow of gas (empirically corrected for the volume occupied by the oil and water vapor in the reaction vessel) and the depth of the catalyst, and integrating the reciprocal of these curves in accordance with the general equation:

$$t = f\int\frac{dL}{V_x}$$

where t = the time factor, or time required to traverse a length L of catalyst, dL = an infinitesimal length of catalyst, f = cross-sectional area of the catalyst tube and V_x = the volume of gas and vapor. The relation between the time factor and the yield of oil resulting from blue water gas at various temperatures, shown in Fig. 308 was obtained by Aicher, Myddleton and Walker. The distinct flattening of the curves at longer periods of contact and high concentrations of liquid is attributed to the adsorption of the products on the surface of the contact agent, thus exercising a retarding action. The curves also indicate that the initial few inches of the catalyst bed perform much more work than the succeeding layers. Thus, the excessive liberation of heat during the reaction is quite likely to develop a "hot spot" which must be guarded against.

EFFECT OF RECYCLING

Since the yield of total liquids is about 55 to 65 per cent of the theoretical, the exit gases contain appreciable quantities of unreacted carbon monoxide and hydrogen. Recycling, that is, passing the exit gas over fresh contact masses, was attempted to increase the yields. Thus, by limiting the extent of initial reaction (such as by using relatively low temperatures, insufficient hydrogen or low gas velocities), condensing the products and returning the remaining gases for further catalytic treatment, the total conversion is said to be increased.[71] However, some doubt as to the economic feasibility of this type of operation has been expressed.[72]

Aicher, Myddleton and Walker[73] have summarized the arguments in favor of a two-stage treatment as follows: (1) There is an increased throughput (i.e., the whole of the contact material is working at higher efficiency and consequently less metal is required for a given output). (2) Increased yield of oil per unit volume of feed gas. (3) By use of different contact materials in the two or more steps, a grading or variation in the unsaturated content of the hydrocarbons may be brought about. (4) The adsorption effect, causing deposition of hard waxes on the catalyst, is retarded. (5) The formation of gaseous hydrocarbons is reduced. The chief disadvantage is that the gas must be cooled after the first stage (to permit removal of the lower-boiling liquid hydrocarbons by treatment with carbon) and the residual gas reheated for a second passage. The volume of the latter gases normally lies between 50 and 55 per cent of the original, but Aicher, Myddleton and Walker point out that there is sufficient heat liberated in the process and in the spent residual

gas to deal adequately and advantageously with the reheating required in the secondary stage.

These same workers[74] have investigated the yield of products obtained by one-, two- and three-stage treatments, using nickel-manganese-alumina-kieselguhr-silica masses. By plotting the results of these tests against the gas velocity, they obtained the curves shown in Fig. 309. Curve *A* refers to the single step treatment (25.5 cc. of catalyst), *B* is that for 2 stages, with the oil and water condensed after both stages and combined (50.9 cc. of catalyst space) and *C* is for 3 successive operations (79.0 cc. of catalyst space). The dotted lines in this figure connect points of corresponding flow for the different volumes of contact mass (or what amounts to the same, equal flow per unit volume of catalyst space) in each of the tests. Thus, considering only the one- and two-step experiments, at higher rates of flow it will be seen that the lines slope downward to the left, indicating that the one stage gave a higher yield than the two stages. However, at low rates of flow the 2-stage method shows a distinctly higher conversion than the former. According to these workers, 3-stage operations are not comparable with the others due to an unfavorable composition of the gas after it has passed through the two preceding treatments.

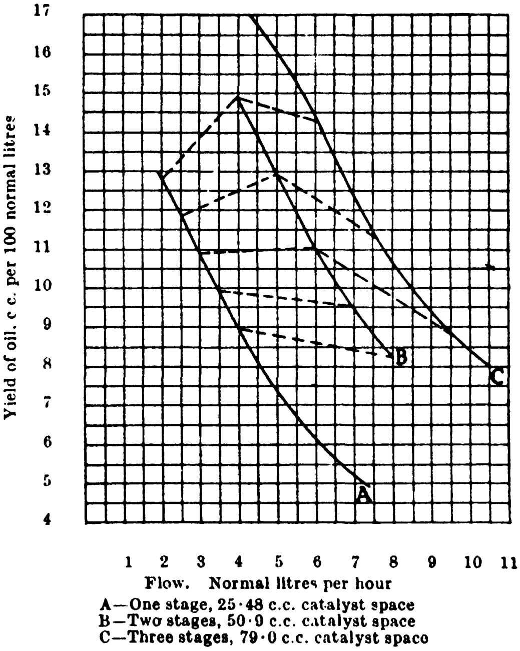

FIG. 309. Influence of Gas Velocity on Yield of Oil from Blue Water Gas in One-, Two- and Three-Stage Treatment. (A. Aicher, W. W. Myddleton and J. Walker)

Courtesy Society of Chemical Industry

Later research by Fischer and Pichler[75] proved definitely that by a step-wise treatment the overall output of liquid hydrocarbons could be increased by 10 to 20 per cent for the same weight of catalyst per volume of gas treated. They found it advantageous to arrange the rates of passage in successive stages to compensate for the gas contraction in such a manner that approximately the same volume of gas passes over the same quantity of catalyst. If the different steps are all carried out at the same temperature, a series of contact masses of successively diminishing activity should be employed. If, on the other hand, a uniformly active material is used, the temperature of the first stage should be somewhat lower than the others. Likewise, the life of the mass is extended somewhat better than in proportion to the number of steps. Fischer and Pichler report that with a 3-stage system a yield of 141 g. of liquid hydrocarbons has been obtained from 1 cubic meter of a gas containing 29.5 per cent carbon monoxide and 60 per cent hydrogen. This represents a 76 per cent conversion, based on the maximum theoretical yield of 185 g. per cubic meter.

PRODUCTION OF METHANE AND OTHER GASEOUS HYDROCARBONS

As was mentioned earlier in this chapter, an increase in either the hydrogen content of the feed gas or in the reaction temperature favors the formation of methane in place of higher hydrocarbons. Certain catalysts, notably nickel, are particularly effective for promoting reduction.[76] Brückner and Jacobus[77] have investigated the addition of silica gel, alumina, thoria, and barium, strontium and calcium oxides to nickel for the reaction:

$$CO + 3H_2 \longrightarrow CH_4 + H_2O$$

at 300°C. The life of the contact mass is thought to be dependent largely upon the extent of formation of higher hydrocarbons, according to these workers. Therefore the inclusion of silica gel, which adsorbs these substances, prolongs the life of the contact material. Their results indicate that mixtures of 90 per cent nickel and 10 per cent alumina or thoria were the best, and that the activity of such mases could be promoted by the addition of alkaline earths, particularly barium oxide. On the other hand, cobalt decreases the effectiveness and copper completely inactivates the catalyst.

With nickel-alumina at 320°C. and a rate of flow of 200 liters per hour per liter of contact material, Karzhavina[78] obtained almost complete transformation of carbon monoxide into methane and carbon dioxide. Rapoport and Blyudov[79] reported a 99 per cent conversion at 270°C. with a nickel contact agent. With nickel-manganese combinations, however, reduction could be carried out at 200-204°C. These investigators noted that appreciable quantities of carbon dioxide resulted only at temperatures above 250°C. and that the simultaneous production of the latter substance and methane was promoted by a nickel-manganese-aluminum contact. Nickel carbonyl is said to exert a similar action, even at 150°C.[80] With molybdenum, no reduction of carbon monoxide occurs at 1 atmosphere pressure, according to Meyer and Horn.[81] At 100 atmospheres pressure, temperatures of about 400°C. are required to effect the formation of methane with molybdenum.

[76] In this respect, B. K. Klimov, V. A. Lanin and Z. T. Tikhonova, (*J. Chem. Ind.* (*Moscow*) **1934** (7), 50; *Chem. Abs.*, 1935, **29**, 321) suggested that the presence of methane in water gas prepared from peat coke is due to the catalytic reduction of the carbon monoxide by the coke.

Padovani[82] has discussed the application of the catalytic conversion of carbon monoxide to methane for the detoxification of gases. He states that at 10 atmospheres pressure and temperatures below 400°C., 85 to 90 per cent yields of methane can be obtained with a complex catalyst such as mixtures of nickel, iron, copper and silica gel.[83] Kemmer[84] proposes to retard the deposition of carbon, due to the reaction

$$2CO \longrightarrow CO_2 + C$$

by saturating the gas at 70°C. with water vapor and passing it over nickel masses at 300-380°C. In addition to the methane reaction, decomposition following the equation

$$CO + H_2O \longrightarrow H_2 + CO_2$$

is said to be effected. However, as Kemmer[85] has pointed out, reduction to methane requires a source of additional hydrogen, since three molecules are involved per molecule of carbon monoxide and would yield a gas of too high methane content. For this reason he suggests a two-step treatment, first interacting the gas with water, in accordance with the equation just given above, by which the carbon monoxide content may be reduced to 1 or 2 per cent. Then, by catalytic reduction, the remainder of the carbon monoxide may be converted into methane.

Perhaps the first evidence as to the possibility of forming higher hydrocarbons from carbon monoxide was that presented by Orlov.[86] He conducted a mixture of equal proportions of carbon monoxide and hydrogen over coke impregnated with metallic nickel and palladium at 95° to 100°C. The reaction product contained 6.6 per cent of ethylene but no methane or formaldehyde. Fischer and Pichler[87] have mentioned that with a silver contact agent or one of magnesite treated with hydrogen, considerable quantities of ethane are produced at high temperatures (600°C.) and pressures (over 70 atmospheres). It is interesting to note that Fuchs and Daur[88] obtained propene by passing a 2:1 mixture of methane and carbon monoxide over glowing pumice and that at 500-550°C. and 240 atmospheres, both propene and liquid hydrocarbons were secured.

PRODUCTION OF LIQUID HYDROCARBONS FROM CARBON DIOXIDE

In 1908, Orlov[89] pointed out that when carbon dioxide was substituted for carbon monoxide at 95° to 100°C. using a catalyst of coke impregnated with nickel, no hydrocarbons were formed. At a low red heat, however, both methane and ethylene were produced. He, therefore, concluded that the carbon dioxide was reduced to carbon monoxide by free carbon in the initial stages of the reaction. Subsequently, Fischer and Pichler,[90] from a study of the influence of carbon dioxide in the hydrogenation of carbon monoxide to liquids with nickel-magnesium-aluminum-kieselguhr combinations reported that interaction was not affected by the presence of the dioxide. Reduction of the higher oxide began only after all carbon monoxide had disappeared and resulted in the formation of methane. The latter observation was confirmed by Schuster, Panning and Bülow.[91]

Küster[92] reduced carbon dioxide to methane at temperatures of about 300°C. by means of a pure iron catalyst. Although the yields were small, the addition of copper, cobalt and nickel promoted reaction, and with cobalt contact masses, higher gaseous and liquid hydrocarbons resulted. A yield of 8.7 cc. of liquid per cubic meter of a $CO_2:3H_2$ mixture was obtained at 215°C. in the presence of a contact agent composed of 5 parts of iron, 5 of cobalt, 0.5 of copper and 1 per cent of potassium carbonate. However, using a ruthenium powder or ruthenium asbestos mass, Fischer, Bahr and Meusel[93] succeeded in reducing a mixture of carbon dioxide and hydrogen to methane at 100°C. By mixing 2 per cent of potassium carbonate with the ruthenium, both higher gaseous and liquid hydrocarbons were formed from carbon dioxide at 180° to 300°C.

Chemical Composition of the Products from Carbon Monoxide-Hydrogen Reaction

The chemical composition of the gaseous, liquid and solid substances obtained from carbon monoxide and hydrogen at atmospheric pressure is limited almost exclusively to two classes of hydrocarbons, paraffins and olefins. The exact proportions of these types can be varied over quite large ranges by the operating conditions. Thus, Fujimura and Tsuneoka[94] reported that although nickel favors the formation of saturates (up to 90 per cent of the total), cobalt on the other hand gives liquids possessing up to 57 per cent olefins. Furthermore, the proportion of gaseous hydrogen in the feed stock has a marked influence, high concentrations also tending towards the production of paraffins.[95]

Gases. Little information is available pertaining to the "Gasol" fraction (boiling below 30°C.). Fischer and Tropsch[96] and also Fischer and Koch[97] mention that this fraction consists of a mixture of hydrocarbons ranging from ethane to pentane. The olefinic content is given by Fischer[98] as 50 per cent by volume. Fujimura and Tsuneoka,[99] however, state that the composition of the exit gases varies greatly; with cobalt catalysts there was a small amount of carbon dioxide and some lower hydrocarbons, but with nickel the latter ranged from 6 to 35 per cent.

Liquids. Tropsch and Koch[100] examined the gasoline fraction obtained by the catalytic treatment of water gas and report that it consisted principally of olefins

(65 per cent) and paraffins. Only traces of aromatics (0.1 per cent of benzene and 0.4 to 0.5 per cent of toluene) and no naphthenes were found. By fractionation and the use of a modified mercuric acetate method,[101] whereby pure olefins were separated, the following hydrocarbons were isolated and identified: pentene-1, pentene-2, hexene-1, hexene-2, 3,3-dimethylpentene-1, heptene, octene-2, nonene, *n*-pentane, *n*-hexane, *n*-heptane, *n*-octane, 3-methyloctane and *n*-nonane. Schaarschmidt and Marder[102] investigated the action of antimony pentachloride on the saturated hydrocarbons in the gasoline fraction and report that about 33 per cent of the paraffinic constituents consist of hydrocarbons containing a tertiary bound atom (such as isopentane and isohexane, for example), which are attacked by this reagent. Even the distillate corresponding in boiling point to *n*-heptane (obtained by repeated fractionation) contained some tertiary carbon atoms. The remainder of the hydrocarbons, which were unaffected by the antimony pentachloride, may have also possessed quaternary bound atoms, according to these workers. Fischer,[103] however, states that there is but little branching in the lower-boiling liquid paraffins.

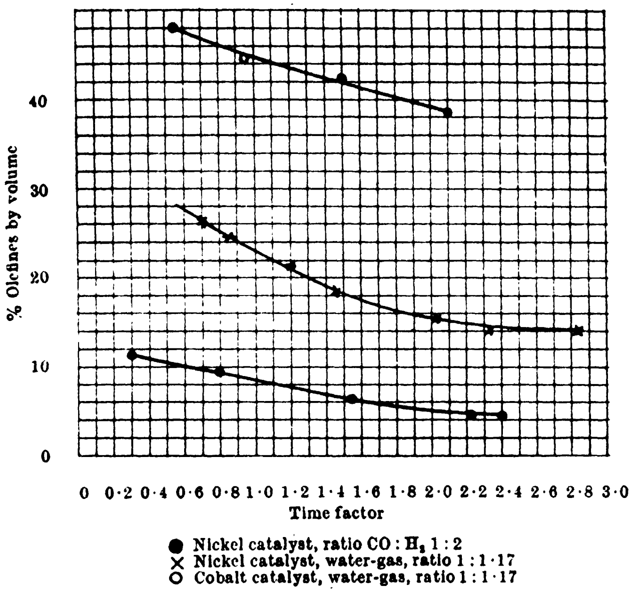

FIG. 310. Influence of Time Factor on Olefin Content of Synthetic Oil from Blue Water Gas. (W. W. Myddleton and J. Walker)

Courtesy Society of Chemical Industry

Tsuneoka and Fujimura[104] report the identification of normal paraffins ranging from pentane to undecane ($C_{11}H_{24}$) in the 30° to 200°C. portion of oil obtained with a nickel-manganese catalyst. The gasoline contained 92 per cent paraffins and 8 per cent olefins. Of the former, *n*-pentane, *n*-hexane, *n*-heptane and *n*-octane were the predominant components. These workers could not detect the presence of either aromatics or naphthenes.

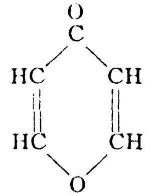
Myddleton and Walker[105] have studied the influence of the so-called "time factor" (mentioned previously in this chapter) on the percentage of olefins in the synthetic oil. Their results with nickel and cobalt catalysts are shown graphically in Fig 310. From this graph, it will be noted that higher proportions of unsaturates are formed with short periods of contact, cobalt rather than nickel contact masses and a deficiency in hydrogen. These investigators used the sulphuric acid-phosphoric acid method[106] for the determination of olefins, after they had established that no more than traces of aromatic hydrocarbons were present. Their work also confirmed the observation of Tsuneoka and Murata[107] that the percentage of unsaturated hydrocarbons decreases with boiling point of the fraction. Tsuneoka[108] has noted that there is a linear relation between the iodine number of the gasoline produced and the hydrogen content of the exit gas. It should be mentioned that Myddleton and Walker[109] found only monolefins in their product. This substantiates the previous observation of Tsuneoka and Murata[110] who had reported the complete absence of diolefins in the reaction mixture.[111]

Small amounts of oxygenated substances are produced even with operations carried out at atmospheric pressure, contrary to statements made by Fischer and Tropsch[112] in 1926. Thus, Tropsch and Koch[113] observed the presence of a substance, thought to be γ-pyrone:



which was separated from the 100-120°C. fraction of the lower-boiling oil. Tsuneoka and Fujimura[114] have investigated the aqueous solution formed in the reaction and report that it contains small quantities of alcohols, aldehydes, ketones and acids. In reference to the latter compounds, Koch, Pichler and Kölbel[115] noted that with cobalt catalysts a yield of 0.35 per cent of acids is produced by side reactions in the hydrocarbon syntheses. In the water layer of the reaction mixture, formic, acetic (about 2/3 of the total), propionic and butyric acids were identified. Unsaturated acids, however, were apparently completely absent. Higher fatty acids, containing 3, 5, 6, 7, 9 and 14 carbon atoms in the molecule were isolated from the oily portion, and amounted to 0.06 per cent by weight of the total Kogasin.

Koch and Ibing[116] have studied the higher boiling (220-350°C.) liquid Kogasin fraction. The oil was partially freed from paraffin wax by cooling to 0°C. and was then hydrogenated to saturate the olefins (4 to 7 per cent of the fraction). Upon repeated fractionation under reduced pressure, about 30 to 40 per cent of the original oil was resolved into *n*-paraffins ranging from decane ($C_{10}H_{22}$) to octadecane ($C_{18}H_{38}$). These were isolated and identified. The remainder consisted of isoparaffins with only slightly branched side chains.

Solids. According to Koch and Ibing[117] the solid paraffins cannot be concentrated with respect to their individual chemical purity by fractional distillation even at 10^{-5} mm. pressure. However, by an extraction method, using different solvents, a possible separation into groups of similar molecular weights and properties is indicated. Thus, the hard paraffin wax (so-called "Ceresin") removed from the catalysts on treatment with ether was resolved into soluble and insoluble constituents, in varying proportions, with minimum and maximum melting points of 40° and 106°C., respectively. The insoluble portion was next extracted with dichloroethylene, which gave products of melting points between 88° and 108°C. and insoluble residues. Upon extraction of the latter with chloroform for 200 hours, substances melting at 112° to 113° and 113° to 114°C. resulted. By renewed extraction with the latter solvent for 187 hours more, solids with melting points of 113-114.5°C. and 115.5 to 116.5°C. and molecular weights of 1750 and 2140, respectively, were isolated. From these experiments, Koch and Ibing concluded that the melting point increases similarly to the carbon-hydrogen ratio of the compounds, and that no homologs of the paraffin series have a higher melting point than about 118°C.

Koch and Ibing have pointed out also that the residues from the chloroform extraction represent the highest members of the saturated aliphatic hydrocarbons yet produced synthetically, and contain from 100 to 150 carbon atoms in the chain. When precipitated from hot benzene solution by alcohol, these appear as a white powder and after melting and solidifying, they are not scratched by the finger-nail. The specific gravity of the paraffin waxes is quite high, ranging from 0.938 for those melting at 40°C. to 0.965 for the largest molecular weight solids. These investigators concluded that the solid compounds are *n*-paraffins, with perhaps some isoparaffins, and have molecular formulas from $C_{20}H_{42}$ to about $C_{150}H_{302}$.

INDUSTRIAL APPLICATION OF THE FISCHER-TROPSCH SYNTHESIS OF HYDROCARBONS

Since about 1934, the rapid commercial development of motor fuel synthesis from carbon monoxide abroad has been phenomenal. It has been predicted that in 1937 half of the German requirements for automobile and aviation fuels will be produced synthetically.[118] This figure is said to be somewhat in excess of 2 billion gallons, or about one-seventh of the U. S. domestic consumption. When it is considered that the annual cracking capacity of German refineries in 1935 was only 121 million gallons,[119] some idea of the expansion along the lines of gasoline production becomes evident.

[119] See Chapter 3.

In general, the Fischer-Tropsch process[120] may be summed up in four essential steps: (1) the preparation of the crude feed mixture, (2) partial desulphurization of the gas to free it of hydrogen sulphide, (3) further desulphurization to reduce the organic sulphur content within prescribed limits and (4) the catalytic treatment. A typical flow diagram for these operations is given in Fig. 311. The individual operations will be considered more in detail subsequently in this section. From Fig. 311 it will be seen that the fundamental procedure is as follows: the feed gas mixture is made in a gas producer of the conventional type by alternately introducing air and steam in a bed of incandescent coke. The gases are washed with water and filtered to remove coal dust and other entrained solid matter, and passed into a primary desulphuretting unit, where hydrogen sulphide is removed. Next the gas is fed into a secondary desulphurizing unit in which organically combined sulphur is eliminated. The sulphur-free gas is now introduced into the catalytic chambers. Here the temperature is maintained between very narrow limits by means of circulating oil. (The temperature used in this stage is dependent upon the nature of the catalyst and other conditions). The hot oil is used for generating steam in a small heat exchanger. The gas and liquid products leaving the contact apparatus are cooled and passed into a separator, where the oil and water are removed. The overhead from the separator is fed into a tower packed with activated carbon (water washing may be used in place of adsorption) to separate the lighter gasoline fractions from the exit gases.

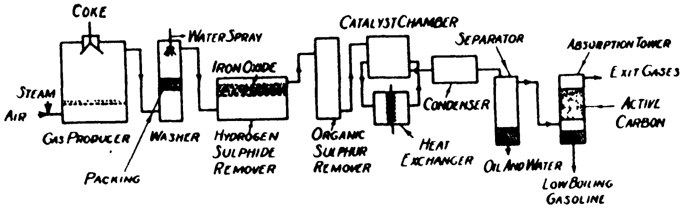

FIG. 311.—Flow Diagram of Fischer-Tropsch Synthesis.

PRODUCTION OF GAS MIXTURE

One of the basic requirements for the commercialization of this process is the availability of enormous quantities of carbon monoxide and hydrogen. These gases may be obtained from many sources as for instance, industrial gases, natural gas or coke. Fischer, Pichler and Reder[121] have discussed this topic and state that the gas mixture may be produced by mixing coke-oven gas with generator gas or with water gas, by direct gasification of coal, or by the interaction of methane, or higher hydrocarbons with steam or carbon dioxide[122] or with oxygen (partial oxidation).

[120] Reviews on the commercial Fischer-Tropsch process have been given by: F. Fischer, *Oel, Kohle, Erdoel, Teer,* 1935, 11, 120; 785; *J. Inst. Pet. Tech.*, 1935, **21**, 170A, 453A; *Chem. Abs.*, 1936, **30**, 3968; *Brit. Chem. Abs.* **B**, 1936, 51; *Brennstoff-Chem.*, 1935, **16**, 1; *Chem. Abs.*, 1935, **29**, 1959; *Brit. Chem. Abs.* **B**, 1935, 179. O. Feldman, *S. African Mining Eng. J.*, 1935, **46** (1), 361; *Brit. Chem. Abs.* **B**, 1936, 915; *Chem. Abs.*, 1935, **29**, 7055. M. Friedwald, *Rev. pétrolifère*, 1935, **634**, 733; *Chem. Abs.*, 1935, **29**, 5626; *Chem. Zentr.*, 1935, 2, 1290; *Brit. Chem. Abs.* **B**, 1936, 1076.

[121] F. Fischer, H. Pichler and R. Reder, *Brennstoff-Chem.*, 1932, **13**, 421; *Brit. Chem. Abs.* **B**, 1933, 49; *Chem. Abs.*, 1933, **27**, 2017. See also N. W. Krase, *Trans. Am. Inst. Chem. Eng.*, 1936, **32**, 493.

[122] See Chapter 10. Also Carleton Ellis, "The Chemistry of Petroleum Derivatives," The Chemical Catalog Co., New York, 1934.

One convenient method of producing these gases is by the well known water gas reaction, by the action of steam on coke at temperatures of about 1000°C.[123] according to the equation:

$$C + H_2O \longrightarrow CO + H_2$$

The resulting mixture thus should contain equal volumes of carbon monoxide and hydrogen, but according to Fischer[124] a 1:2 ratio of these gases (which has been found to be optimum) can be obtained by gasifying at low temperatures in the presence of a larger quantity of steam, in accordance with the equation:

$$H_2O + CO \longrightarrow H_2 + CO_2$$

The hydrogen deficiency in water gas can be made up in a number of other ways. For instance, Fischer, Pichler and Reder[125] reported that in the presence of a nickel catalyst, methane will react with steam at 800°C. and 1 atmosphere or 600°C. and 0.1 atmosphere pressure (at times of contact of less than 1 second) to give carbon monoxide.

$$CH_4 + H_2O \longrightarrow CO + 3H_2$$

Thus, by combining the water-gas reaction with the latter, a mixture of carbon monoxide and hydrogen in the proportion 1:2 can be formed. Likewise, the thermal decomposition of methane

$$CH_4 \longrightarrow C + 2H_2$$

may be utilized to augment the hydrogen content of the water gas.[126] Deficiencies in carbon monoxide may be made up by secondary reactions involving the reduction of carbon dioxide.[127] The latter may be accomplished in a variety of ways, as with coke,

$$CO_2 + C \longrightarrow 2CO$$

or with copper.[128] The possibility of using electrolytic hydrogen and carbon dioxide from gas wells has also been considered by Fischer.[129] From this discussion it will be seen that quite a wide variety of reactions are applicable for production of the feed stock gases.

Fischer, Pichler and Reder[130] suggested forming the gas mixture by passing coke-oven gas and steam over incandescent coke. In these experiments, a small water-gas generator was used, and the fuel bed alternately blown with air for 1 minute and then subjected to the action of the mixed steam and coke-oven gas for 3 minutes. The resulting gas had the composition: 2.4 per cent carbon dioxide, 0.4 per cent oxygen, 28.2 per cent carbon monoxide, 52.3 per cent hydrogen, 2.5 per cent methane and 14.2 per cent nitrogen. This mixture was reported to give a yield of 26.4 per cent gasoline based on the quantity of coal used. Subsequent work by

Fischer, Pichler and Kölbel[131] with a gas producer of 100 cubic meters per hour output showed that the ratio of carbon monoxide to hydrogen could be raised to 1 :2. This was accomplished by increasing the gasifying time to 4 minutes instead of the 3 minutes used in the earlier tests. The carbon dioxide content was reduced to 0.6 per cent and that of methane to 0.4 per cent. However, with a 1 minute blast and a 6 minute gasification period, the latter figures increased to 0.9 and 1.1 per cent respectively.

The theoretical yield of oil naturally depends upon the composition of the gas, the highest theoretically possible being given by a gas containing 33.3 per cent carbon monoxide and 66.6 per cent hydrogen. However, Fischer and Meyer[132] have used coke-oven gas, with a carbon monoxide content of only 5 to 6 per cent and obtained 22 cc. of total liquids (75 per cent of which boiled in the gasoline range) per liter of feed gas, using a nickel-manganese-aluminum catalyst. Aicher, Myddleton and Walker[133] have prepared a list of the common industrial gases together with the per cent of carbon monoxide available (i.e., with the necessary hydrogen for a 1 :2 ratio) and the theoretical yield of oil in gallons per 1000 cubic feet of gas, as is given in Table 232. According to these investigators, commercial yields of liquid hydrocarbons cannot be attained from gases containing less than about 24 per cent of carbon monoxide and 48 per cent of hydrogen.

TABLE 232.—*Theoretical Yields of Oil Obtainable from Industrial Gases in the Carbon Monoxide-Hydrogen Synthesis.*

	CO, Vol.% Available with Necessary H_2	Theoretical Yield of Oil in Gallons/1000 cu.ft. of Gas
Coke-oven gas	5.5	0.31
Cracked gas (coke-oven gas treated with steam at 900°C.)	19.2	1.09
Water gas	24.0	1.36
Water gas and coke-oven gas	25.3	1.43
Special water gas made at a lower average temperature	29.0	1.64
Cracked coke-oven gas and water gas	30.4	1.72

Sulphur Removal. All commercial gases contain sulphur, either as hydrogen sulphide or as mercaptans or in other chemical combinations, which exert a serious deactivation effect on the catalyst. According to Fischer,[134] the total sulphur content must be reduced to less than 0.2 g. per 100 cubic meters (approximately 0.1 grain per 100 cubic feet). This is usually done in two stages, (as indicated in the flow diagram, Fig. 311), the first for the removal of hydrogen sulphide and the second for organically combined sulphur. Desulphuretting is accomplished by passing the gas over layers of iron oxide. Details on the removal of the organic sulphur (second stage) in the commercial process are not available at present, however Aicher, Myddleton and Walker[135] have described a catalytic method which they used on a semi-commercial scale. The mercaptans and other sulphur-containing compounds are reduced to hydrogen sulphide by hydrogenation over a catalyst. The latter is prepared by mixing equal parts of copper oxide and lead chromate, adding a solution of ethyl orthosilicate in toluene, and pressing the paste into rods ¼ inch in diameter which are broken into convenient lengths. After several days exposure to moist air, to cause hydrolysis of the silicate ester and thereby obtain the desulphiding catalyst on a durable but porous support of silica, the mass is charged into iron tubes (about 2 or 3 inches in diameter) and reduced by passing the gas mixture through at a temperature of 370-400°C. for several hours. Hydrogen sulphide resulting from this treatment is removed by again passing the gas over a bed of iron oxide. In this manner it was possible to reduce the sulphur content of some gases from 30 grains per 100 cubic feet to approximately 1.1 grains per 100 cubic feet. The latter figure is still much too high, and therefore the gas was subjected to a second catalytic treatment. Instead of removing the hydrogen sulphide resulting from this operation with iron oxide, an alkaline solution of potassium ferricyanide was used. By this procedure, the sulphur content was lowered to about 0.1 grain per 100 cubic feet. According to these workers, the catalyst proposed showed no loss in activity during several months of continuous operation. The potassium ferricyanide solution, however, required continuous electrolytic oxidation to maintain it at working strength. Treatment at 150-300°C. with a catalytic mixture of 5 to 10 per cent of an alkali carbonate with oxides or hydroxides of iron has also been suggested for the removal of organic sulphur compounds.[136]

CONTACT AGENTS

The catalysts recommended by Fischer[137] for commercial operations are of the cobalt type. Cobalt-thorium-kieselguhr (18 per cent Th), made by precipitation of the nitrates with sodium carbonate, are said to be among the best. (Similar masses formed by thermally decomposing the nitrates may also be used, but have a much shorter active life.) The cobalt-thorium-copper-kieselguhr catalysts (2 per cent of copper) are also employed since they can be reduced at very low temperatures. With contact materials of these types, yields of 100-130 grams of liquid hydrocarbons are obtained per cubic meter of the special water gas mentioned previously. Conversion is about 56 to 72 per cent of the theoretical (180 grams). Fischer states that the yield will undoubtably be greatly increased in the future after sufficient experience has been accumulated. He is also of the opinion that iron may eventually replace cobalt for large scale operation. Silica gel or asbestos may be substituted for kieselguhr in the contact masses, according to Friedwald.[138] Notwithstanding careful purification of the gas to lower its sulphur content to 0.2 g. per 100 cubic meters, poisoning of the catalyst cannot be avoided in runs of long duration. Fischer and Meyer[139] have proposed to compensate for this deactivation with nickel catalysts (which completely absorb the sulphur in the gases) by increasing the reaction temperatures slowly, about 25°C. over a period of 4 weeks. After this time has elapsed, however, a complete reconditioning of the catalyst is necessary. Fischer and Koch[140] noted that cobalt-thorium combinations in continuous operation for 63 days lost only 10 per cent of their initial activity. Nevertheless, Fischer[141] has stated that the catalysts gradually become deactivated, probably due to recrystallization, i.e., the particles are thought to increase in size and there are then fewer points of catalytic activity. Furthermore, in all extended operations, the contact mass becomes saturated with a hard paraffin, which often loads the catalysts down to several times its own weight. Friedwald[142] asserts that this accumulation of paraffin apparently exerts no depreciatory effect on the activity of the mass. This statement, however, is contradictory to that of Fischer and Koch[143] who reported that the 10 per cent loss in activity of the cobalt-thorium mass just mentioned previously was completely restored by the extraction of the paraffin wax which had been deposited thereon. The regeneration process generally employed consists in dissolving the paraffin and treating the contact mass with nitric acid to dissolve the metals, filtering and reprecipitating.

[141] F. Fischer, *Oel, Kohle, Erdoel, Teer*, 1935, **11**, 120; *J. Inst. Pet. Tech.*, 1935, **21**, 170A.

The catalytic material is packed into chambers around which, by means of jackets, a stream of oil is circulated. According to Friedwald,[144] temperatures of 190° to 195°C. are used for the cobalt-mixed type catalysts. The excess heat in the circulating oil is employed for generating steam. This utilization, which amounts to about 20 per cent of the heat of combustion of the initial feed gas, represents a considerable saving on the amount of fuel consumed.

In passage through the reactor a contraction of about 75 per cent of the initial volume of the gas is evidenced. After cooling the reaction mixture down to room temperature, it is introduced into a separator, from which the water and major portion of the liquid hydrocarbons are withdrawn. The hydrocarbon portion is subjected to distillation into four fractions: gases, liquids, applicable as motor fuels, higher-boiling liquids and a solid paraffin wax. Additional wax of a higher melting point is recovered from the catalyst. By passing the vapors leaving the separator through a tower filled with activated carbon (or adsorbent charcoal) the lower-boiling liquid hydrocarbons are stripped from the exit gases.

The primary products and the yields (in weight per cent) obtained in commercial operation have been given by Fischer[145] as:

Gasol (boiling below 30°C.)		8%
Gasoline (boiling range 30–125°C.)	37%	
" (" " 125–200°C.)	25%	
		62%
Lamp and Diesel oil (boiling over 200°C.)		24%
Solid paraffin wax from oil (melting point over 50°C.)		2%
Solid paraffin wax from catalyst (melting point over 100°C.)		4%
		100%

The proportion of liquids boiling in the gasoline range (30-200°C.), 62 per cent, amount to nearly two-thirds of the total. In addition, Diesel oil consitutes almost one-quarter of the total.

USES OF PRODUCTS OF THE CARBON MONOXIDE-HYDROGEN SYNTHESIS

No doubt the chief motivant instigating the majority of the numerous researches on the synthesis of higher hydrocarbons from carbon monoxide and hydrogen was the hope of attaining a synthetic motor fuel. In general, however, the gasoline obtained has a relatively low octane number, ordinarily about 47, according to Fischer.[146] But as Feldman[147] has pointed out, the complete absence of sulphur in the liquid product, Kogasin, makes the latter an ideal man-made petroleum stock.

[147] O. Feldman, *S. African Mining Eng. J.,* 1935, **46** (1), 361; *Chem. Abs.,* 1935, **29**, 7055; *Brit. Chem. Abs.* **B**, 1936, 915.

He is of the opinion also that the only natural petroleums approaching the synthetic Kogasin in quality are those of the sulphur-free paraffin base type.

Gasoline. Myddleton and Walker[148] have discussed the characteristics of the synthetic gasoline (boiling up to 150°C.) fractionated from Kogasin. These investigators found that the octane number of this motor fuel increases greatly with the olefinic content, as is shown in Fig. 312. Thus, a liquid with 60 per cent of unsaturates, had an octane rating of 65 (C.F.R. motor method), whereas with one containing only 10 per cent, the octane value was only 25. It is therefore apparent that the olefinic content should be relatively high for possible utilization of this material as gasoline. Koch and Horn[149] have separated the lower-boiling Kogasin portion (below about 150°C., and having an octane number of 58) into 10°C. fractions and determined the antiknock rating and olefinic content of each cut. The lowest-boiling fraction contained 46 per cent unsaturates and had an octane number of 85, but for the highest-boiling portion the values dropped off to 23 per cent and 41.5 octane, respectively. For comparative purposes, an examination of a cracked gasoline (from natural petroleum) of substantially the same characteristics was made. The results of these tests showed that although the percentage of unsaturates in the different fractions of the latter was roughly constant, the antiknock rating also fell off with rising boiling point, but not as rapidly as with the synthetic mixture. According to Friedwald,[150] by blending the synthetic gasoline with benzene or with 10 to 20 per cent of alcohol, or by the addition of 0.05 per cent of lead tetraethyl, the octane number can be increased considerably, in the latter case to 80.

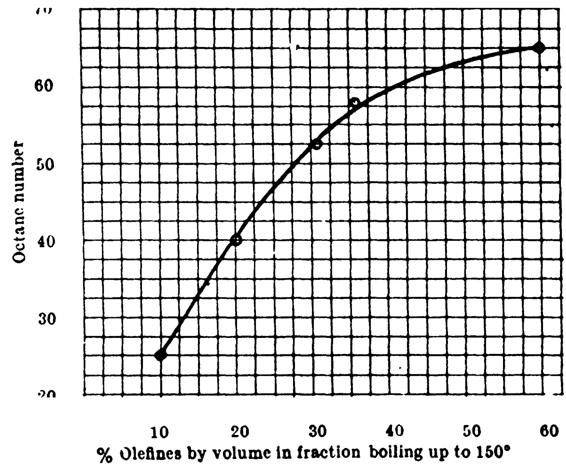
Effect of Olefin Content on Octane Rating of Synthetic Gasoline. (W. W. Myddleton and J. Walker)

Courtesy Society of Chemical Industry



Several proposals utilizing high pressure treatment have also been advanced for the manufacture of motor fuels from carbon monoxide and hydrogen. In most instances, the pressures are about 200 atmospheres and temperatures of 450-500°C., with catalysts of zinc oxide and chromic oxide.[151] Higher alcohols, however, are the main products of these reactions. By dehydration to olefins (with catalysts such as alumina at 300°C.), polymerization and hydrogenation, the latter may be converted into motor fuels. The reduction of carbon monoxide to liquid hydrocarbons under pressures of 20 atmospheres is also said to be effected in the presence of anthracene oil.[152]

Cracked Gasoline from Kogasin. Fischer[153] has suggested increasing the knock-resistance of the lower boiling Kogasin fraction by reforming[154] or cracking it to aromatic hydrocarbons. He states that high octane fuels are secured by cracking the higher boiling portions of Kogasin I (125° to 200°C.) Kogasin II (boiling over 200°C.) or even the wax material separated from the oil by cooling.[155]

Pichler[156] investigated the thermal conversion of the heavy oil (boiling from 240° to over 320°C., and corresponding to 10-20 per cent of the total oil produced in the synthesis) to unsaturated and aromatic hydrocarbons, using tubes 8 to 17 mm. in internal diameter, electrically heated to 500-700°C. Below 500°C., the reaction was quite slow, whereas above 600°C. gaseous olefins predominated. The yield of the latter rose rapidly with the temperature, from 20 per cent at 550°C. and a reaction time of 0.4 second to 62 per cent at 700°C. and 0.14 second. From 50 to 75 per cent of the oil was cracked into gaseous and low-boiling unsaturated and aromatic hydrocarbons, the remainder consisting of gaseous paraffins, unchanged oil and aromatic tar. By controlling the reaction time, no appreciable deposition to carbon is said to occur.

A study of the cracking of Kogasin II (boiling above 200°C.) has also been conducted by Peters and Winzer.[157] After removal of most of the solid paraffin, the stock had a specific gravity of 0.878; 57.6 per cent distilled between 200 and 300°C. A series of experiments was made cracking this material under various pressures. With temperatures below 560°C. (1040°F.), yields of liquid products from 50 to 80 per cent resulted. Aromatics, such as benzene, did not appear in the reaction mixture, however, unless the temperatures were in excess of 550°C. It was noted that at 530°C. and 80 atmospheres pressure, the quantity of gases produced could be reduced by about 75 per cent by tripling the rate of feed. Increase in pressure at constant temperature improved the yield of liquids, but with the same reaction time, more gases resulted. The cracked gasolines were highly unsaturated. Hydrogenation reduced their copper-dish gum values from 260 or 270 mg. to 43 mg. per 100 cc. However, the latter treatment also lowered the octane number to 48.5.

Incorporation of ethylene or cracked gas with the unsaturated gasoline obtained in the above tests was also investigated by Peters and Winzer,[158] using kieselguhr impregnated with phosphoric acid as catalyst. In one test, ethylene was charged into an autoclave to a pressure of 55 atmospheres, and heated to 330°C. After a few hours the pressure dropped from 270 to 100-150 atmospheres. Examination of the resultants indicated that ethylene alkylated the gasoline instead of polymerizing and the motor fuel obtained had an octane rating of 63.5. The investigators state that by cracking Kogasin II in the presence of a phosphoric acid catalyst, the yield of gasoline was increased from 21 to 30.6 per cent by volume.

Diesel Oil. According to Fischer,[159] Kogasin II (boiling above 200°C.) makes an ideal Diesel fuel after the dissolved solid paraffins have been separated. Because of its high hydrogen content, it is said to give a somewhat higher mileage than the fuel from commercial gas oil.[160] Diesel oils of low pour points were made by Koch and Ibing[161] by cooling Kogasin II to temperatures of —10°, —20°, and —30°C. to remove the higher melting solid paraffins. The minimum yields of fuels with cloud points of the above temperatures obtained from this oil are given as 78, 62.5 and 45 per cent respectively.

Lubricating Oils. Although there are no fractions in Kogasin corresponding to the natural lubricating oils, Fischer[162] has enumerated three ways in which they can be synthesized. These are: (1) by condensing the lower boiling fractions, rich in olefins, with aluminum chloride. (2) by forming olefins from the saturated paraffins (such as by halogenation and subsequent dehalogenation) and catalytic condensation and (3) by condensing chlorinated fractions with aromatic hydrocarbons, according to the Friedel-Crafts reaction.

With regard to the first method, Fischer and Koch[163] suggested the use of Kogasin I, the low boiling fraction which contains about 35 per cent of unsaturates. Preparation of lubricants from Kogasin II, according to the second of Fischer's suggestions, has been discussed by Koch and Ibing.[164] These investigators point out that a uniform raw material is essential, and therefore subjected the oil to repeated fractionations at reduced pressure. By this treatment, isopentadecane was isolated from Kogasin II, and afterwards was chlorinated, mixed with about 10 to 15 per cent of the unchlorinated hydrocarbon and treated with 4 per cent of activated aluminum. The small quantities of aluminum chloride formed attack the alkyl chloride and cause hydrogen chloride to be evolved. The latter reacts with the metallic aluminum to form more aluminum chloride and this accelerates the rate of reaction. At 150°C., interaction followed three distinct courses. First, the catalyst caused cracking, as was evidenced by the presence of about 8 per cent of lower-boiling hydrocarbons (nonane and dodecane) in the product. Secondly, elimination of hydrogen chloride followed by intermolecular displacement of hydrogen led to the formation of the original hydrocarbon. Thirdly, polymerization and condensation were evidenced by the nature of the substances formed, which contained 1 double linkage and 1 or 2 naphthene rings.

The last method, a typical Friedel-Crafts reaction,[165] has been investigated by Fischer and Koch.[166] By chlorinating Kogasin II, substituted hydrocarbons containing up to 6 chlorine atoms were obtained. The latter were separated, mixed with about 1 to 3 volumes of an aromatic hydrocarbon (xylene, benzene, toluene, naphthalene, α-methylnaphthalene and also tetrahydronaphthalene were employed in these tests), and about 5 per cent of aluminum chloride, based on the weight of the chlorinated stock, added. Reaction began in the cold and was accelerated by stirring and warming on a water bath. The product was freed from the reaction mixture by washing, and was treated with a small quantity of fuller's earth, after which excess aromatic hydrocarbons and unreacted low boiling materials were removed by distillation. The lubricants are said to contain less than 0.1 per cent of chlorine and to have an average molecular weight of about 450. Those resulting from the trichloro Kogasin derivatives contained about 2 aromatic rings per molecule and had properties similar to those of an asphaltic base lubricating oil (such as Texas oil). No advantage was gained by using the more highly chlorinated fractions, as the condensates were too viscous.

Subsequent work by Koch and Ibing[167] on the aliphatic halide-aromatic condensation show that best results are obtained when the starting material is homogeneous, which can be brought about by repeated low pressure fractionation. The procedure advocated by these investigators is to mix monochloro-*n*-tetradecane containing about 10 per cent *n*-tetradecane with an equivalent weight of xylene and 10 per cent of its weight of aluminum chloride. The resulting lubricating oil (about 30 per cent yield) was water-white, with a blue fluorescence and had a specific gravity of 0.8610. The molecular weight corresponded not to tetradecylxylene, but to tridecylxylene, indicating the loss of a CH_2 group, which apparently had split off during the condensation. Similar experiments were repeated by Koch and Ibing in a study of the effect of milder conditions on the yield. But even with *n*-tridecane, benzene and only 5 per cent of aluminum chloride the reaction was violent and cooling with ice water was necessary. No low-boiling products of cracking were present in the reaction mixture, but the lubricating oil fraction (water-white with a bright bluish fluorescence) corresponded in its properties to dodecylbenzene, so that once more indications pointed to a splitting of a methylene group from the paraffin chain. Two higher boiling portions corresponding to the general formulas C_nH_{2n-8} and C_nH_{2n-14}, respectively, were also separated and found to have satisfactory viscosity-temperature coefficients. The latter substances are thought to have arisen from the union of benzene and dichlorinated paraffins which may have been present in the starting material. Koch and Ibing conclude that smaller proportions of aluminum chloride and temperatures below 100°C. give the optimum conversions to alkyl benzenes.

Fischer[168] has compared the properties of a winter grade commercial type motor oil with those of one made from Kogasin, as is shown in Table 233.

TABLE 233.—*Comparison of Commercial Motor Oil with Kogasin Lubricating Oil.*

	Winter Grade Commercial Motor Oil	Synthetic Kogasin Lubricating Oil
Sp.gr. at 20°C.	0.882	0.838
Viscosity at 20°C. (°Engler)	32.6	32.0

Other Uses. Fischer and Koch[169] have suggested converting the olefins of the "Gasol" portion into alcohol and utilizing the remaining gases as fuel. An alternative procedure is to heat Gasol to 1000°C. with short reaction times to produce illuminating gas and aromatic hydrocarbons.[170] The latter may be used for blending with the lower octane number motor fuel produced in the Kogasin synthesis. Polymerization of the olefinic constituents to form liquids of the "polymer gasoline" type[171] by treatment with catalysts such as phosphoric acid, zinc chloride and boron trifluoride has also been suggested.[172]

Paraffin wax separated from Kogasin' II is adapted for the manufacture of candles, and because of its high purity, can also be employed as an intermediate for the production (by oxidation) of carboxylic acids.[173] The hard paraffin wax (so-called "Ceresin") removed from the catalyst has good dielectric properties and is therefore applicable as electrical insulation. According to Graefe,[174] a synthetic ceresin (melting point 96°C.) is much more difficultly liquefied by the addition of solvents than is the natural ceresin, paraffin or montan wax.

ECONOMICS OF THE KOGASIN PROCESS

The extensive equipment adapted to the requirements of large scale operation in the United States demands an installation cost not in keeping with a country still possessing vast supplies of natural petroleum. For those countries which seek to be self-sustaining in all respects there may be some justification, on nationalistic grounds, for the erection of Fischer units. But as yet such a process apparently cannot well compete with natural petroleum, both as to cost of production and with respect to the octane value of the gasoline fuel obtained.[175]

[175] According to M. Friedwald (*Rev. pétrolifère*, 1935, **634**, 733; *Chem. Abs.*, 1935, **29**, 5626; *Chem. Zentr.*, 1935, **2**, 1190; *Brit. Chem. Abs.* **B**, 1936, 1076), the price of the initial investment in the Fischer process is less than that of the Bergius method, which involves the direct hydrogenation of coal. (The principles underlying the latter type of operation have been discussed by Carleton Ellis, "Hydrogenation of Organic Substances," D. Van Nostrand Co., Inc., New York, **1930**.) The construction cost in France for a Kogasin unit capable of producing 25,000 tons of gasoline per annum is estimated at 40 million francs (*Chem. Trade J.*, 1936, **98**, 286; *J. Inst. Pet. Tech.*, 1936, **22**, 265A).

Chapter 53

Petroleum Hydrocarbons in Anesthesia

Although anesthesia is most often induced by ether or by various local anesthetics, such as the *p*-aminobenzoates, some gases are being used quite widely for a general narcosis. For example, a number of the hydrocarbon gases, including ethylene, acetylene and cyclopropane, have also found application in this field.[1] The anesthetic effect of gasoline vapors was described in 1920 by Haggard.[2] He observed that, although the vapors possessed an anesthetic action somewhat like diethyl ether, they also had marked convulsant properties. This was considered to appertain to the same stage of anesthesia as is marked by excitement during the administration of ether. Haggard also showed that the stage of full anesthesia was quite narrow, that is, shortly after unconsciousness ensued, the vapors were toxic. The toxicity of gasoline vapors was not, however, in any sense as great as that of the carbon monoxide produced by incomplete combustion in a gasoline engine.

Brown and Henderson[3] have observed that the alkanes (methane and propane) cause complete anesthesia only in such large concentration (90 to 93 per cent) that there are cardiac irregularities and a drop in blood pressure. Pentane possesses narcotic properties also, but the anesthetic and toxic doses are very near together.

Butane is reported to have less anesthetic activity and lethality than pentane. Also, branched isomers of each of these hydrocarbons are said to be less active than the straight-chain compounds.[4] Experiments with rats and with humans have indicated that natural gas in concentrations up to 30 per cent in air has no apparent effect on the body functions.[5] However, concentrations of 60 and 80 per cent in oxygen caused the animals to lose muscular control to some extent and to assume a state resembling drunkenness. Recovery was very quick on restoration to air and no after effects were noted.

ETHYLENE AS AN ANESTHETIC

In 1923, Luckhardt and Carter[6] investigated the physiologic effect of ethylene on dogs and also on men. They reported that a deep surgical anesthesia was rapidly produced and that analgesia came on very early. There was said to be no apprehension of asphyxia and very few symptoms, such as nausea and cyanosis, which might cause danger or discomfort. By using mixtures of ethylene and oxygen it was shown that narcosis results from the former, and that the asphyxial phenomena produced by the undiluted gas are due to the lack of oxygen. Subsequently a report was made of the result of employing ethylene in 106 surgical cases.[7] In these, difficulty was encountered in only two cases, in which surgical anesthesia could not be induced. Luckhardt and Carter noted the advantages which ethylene had over nitrous oxide and diethyl ether. Their results were confirmed by Brown and Henderson[8] who also noted that toxic doses caused failure of respiration and the vasomotor center, and that the cardiac death was due to asphyxia.

---

[1] The action of acetylene, ethylene, propene and butene on various insects and on plants has been investigated by P. W. Zimmerman, *Contr. Boyce Thompson Inst.*, 1935, **7**, 147; *Chem. Abs.*, 1935, **29**, 7005.

According to Lundy[9] ethylene could be used advantageously in nearly all types of surgical risks. He stated that it had less effect on cardiovascular balance than other local and general anesthetics which were commonly employed. Among other advantages which have been noted for ethylene[10] are ease of induction, rapid recovery, absence of sweating and of respiratory irritation. As a result of 521 cases in which it was used, Brumbaugh[11] found that one of the disadvantages was that there was somewhat greater tendency for the oozing of wounds than with other anesthetics, although this stopped when the gas-supply was withdrawn.

Ethylene has been employed successfully in special fields. Thus, it has been used with good results in obstetrics,[12] in which it is said to be superior to diethyl ether or nitrous oxide.[13] On the other hand, Gwathmey reports that the anesthetic value of ethylene seems to fall between nitrous oxide and ether.[14] He believed that premedication with Epsom salts and morphine was desirable.

In dental surgery there has been some application of this unsaturated hydrocarbon. Moravec[15] believed it of value in cases where there is chronic hypertension and that it may be used simultaneously with nitrous oxide to promote relaxation. On the other hand there was some danger if anoxemia (lack of oxygen in the blood) occurred without cyanosis.[16] However, Selden[17] observed that there was some danger of asphyxia or explosion when using ethylene with other gases such as carbon dioxide or oxygen. On the other hand Christiansen[18] recommended a mixture containing 10 per cent oxygen and 90 per cent ethylene as a general anesthetic in dentistry. In cases in which the time for operative working was more than 5 minutes, the proportion of oxygen in the mixture could be raised to 20 per cent or more. He reports much the same results as were obtained in the cases mentioned previously, that is, anesthesia was readily effected and maintained, recovery was rapid and there was no excitement either during induction or recovery. Muscular relaxation was produced without cyanosis. There was no respiratory irritation, excessive perspiration or post-operative disturbance, and nausea occurred only rarely.

One of the dangers which is attendant upon the use of ethylene and mixtures in which it is a component is the explosive nature of the hydrocarbon gas when admixed with oxygen or air. This danger was recognized by the users, and appropriate precautions were taken. Brown[19] has tended to minimize this danger by showing that it requires 40 to 45 per cent pure oxygen or 90 per cent air (about 21 per cent oxygen) in mixture with ethylene to reach explosive proportions. Ordinarily but 10 to 25 per cent of oxygen is used in the anesthetic mixture. He further observed that it would require about 6 hours of continuous anesthesia for ethylene from the spill valve to produce an explosive mixture in a room 15 feet square and 12 feet high. Luckhardt[20] points out that there is some possibility of igniting ethylene-oxygen mixtures by hot cauteries or by static sparks. He observed that there was the same danger in using ether-oxygen or ether-nitrous oxide-oxygen mixtures and that the equipment in the operating room must be so designed as to prevent such an occurrence.

A method for eliminating the danger of explosions due to static sparks has been proposed by Lewis and Boehm.[21] All the objects in the immediate range of the operating table are grounded, as well as the persons about the table and the patient. The reducing valve on the tank and the mixing chamber are connected by a wire. Both ends of the breathing tube are connected by means of a bare wire running inside the tube. A moist cloth establishes contact between the metal of the mask and the patient's face, and a light brass chain runs from his arm to the metal part of the table. An insulated wire connects the table with the machine which is grounded by means of a heavy moist cloth. The anesthetist and other persons present stand on a large moist bath mat which is grounded. In this way there should be no danger of the formation of any sparks which could cause an explosion.

According to Poe[22] elimination of hazard due to sparks is effected by causing rebreathing of the ethylene mixture which is added after unconsciousness is first brought about using nitrous oxide and oxygen. After five or six breaths are exhaled into the rebreathing bag the relative humidity is 100 per cent, and, since 55 to 65 per cent humidity will dispel static electricity, there is said to be no danger under these conditions.

As has been stated earlier in this chapter, the use of ethylene alone is likely to cause asphyxia, and it is consequently the customary practice to employ ethylene and oxygen simultaneously. As a result of experiments carried out on rats, rabbits, dogs and other animals, Goldman found[23] that anesthesia did not occur until there was 12 per cent or less oxygen with the ethylene. He also noted that the content of oxygen could be as high as 20 or 30 per cent when acetylene was substituted for the olefin. Other mixtures, such as acetylene-nitrous oxide-oxygen and acetylene-ethylene-oxygen were tried and were fairly satisfactory agents. Parker and McDonald[24] have studied the application of mixtures containing ethylene, nitrous oxide and oxygen. When the gases were rebreathed with no filter to remove the carbon dioxide which was exhaled, the oxygen concentration remained practically constant and the average concentration of ethylene was slightly higher than that of the nitrous oxide. On the other hand, when a carbon dioxide filter was present, there was a gradual accumulation of oxygen and the average concentration of nitrous oxide was the higher. It is interesting to note that Kleindorfer[25] has reported that 5 to 10 per cent of carbon dioxide has an additive effect on the anesthesia produced by subanesthetic concentrations of ethylene.

In this connection also the technique of rebreathing a gas mixture should be mentioned. The essential feature of this method is that the same mixture of gases is used throughout the period of anesthesia.[26] Carbon dioxide is removed with the aid of a canister of soda-lime and oxygen is supplied continuously to replace that used by the patient. Changes in composition of the mixture are effected by the anesthetist by admitting either oxygen or anesthetic as required. One advantage of this method is the economy of anesthetic. This permits the use of a more expensive anesthetic without prohibitive cost to the patient. Furthermore there is less contamination of the air breathed by the surgeon and assistants, and less danger of the formation of explosive mixtures in the air of the room. For example, cauteries may be performed if sufficient care has been exercised in freeing the anesthetic mask from leaks. This is also of advantage in experimental work, Waters,[27] for example, having reported that by use of this technique he was able to use trimethylethylene as an anesthetic in more or less duplication of Snow's work.

Ethylene in conjunction with still other compounds has been proposed as an anesthetic. Thus, Cheney[28] suggested that the olefin be mixed with 0.5 to 5.0 per cent of ether vapor. The gases may be liquefied under 1000 pounds pressure or more. Ethylene has been used successfully in conjunction with avertin (tribromoethanol).[29] In this instance, however, it was found that the power of the blood to combine with carbon dioxide was slightly decreased, and the sugar-content of the blood was slightly increased.

ANALYSIS OF ETHYLENE FOR ANESTHESIA

A gas intended for use in anesthesia cannot be too pure when employed on human patients. The report of Sherman, Swindler and McEllroy[30] of deaths from carbon monoxide poisoning after ethylene anesthesia showed the dangers inherent in a product of uncertain purity. Many tests for impurities have been investigated by The Medical Association Laboratory and those which are considered of importance are:[31] the behavior of the gas toward methyl red and absence of carbon dioxide (tested with barium hydroxide), acetylene, phosphine, aldehydes and hydrogen sulphide (tested with ammoniacal silver nitrate). The proportion of ethylene is determined by absorption in bromine water. Oxygen and carbon monoxide may be determined by absorption in alkaline pyrogallol and an ammoniacal or hydrochloric acid solution of cuprous chloride, respectively. In samples from two manufacturers whose products were accepted, the methyl red, ammoniacal silver nitrate and barium hydroxide tests were all negative. The results are shown in Table 234 where Samples 1 and 3 are from one and 2 and 4 from the other producer.

The methods which have been recommended for the analysis of ethylene by Busi and Collina[32] differ from those used by the A.M.A. Laboratory in shaking the reagent and gas rather than bubbling the gas through the reagent. In testing for carbon dioxide the gas is sampled in a bulb of approximately 500 cc. capacity. To

TABLE 234.—*Composition in Per Cent of Ethylene for Anesthesia.*

Sample	Ethylene	Residual Gases	Oxygen	Carbon Monoxide
1	99.37	0.63	0.13	0.00
2	99.42	0.58	0.58	0.00
3	99.15	0.85	0.18	0.00
4	98.93	1.07	0.23	0.00

the flask is added 5 cc. of a saturated solution of barium hydroxide. A precipitate should form on agitation if there is 1 part of carbon dioxide to 5000 of ethylene. Similarly, a solution of 1 or 2 drops of methyl red in 5 cc. of distilled water is shaken with the sample. There should be no acid reaction.

Acetylene forms a white precipitate when a sample of ethylene (containing as little as 1 part in 20,000) is shaken with an alkaline solution of potassium mercuric iodide. This precipitate blackens in the presence of phosphine, arsine or stibine. An ammoniacal solution of silver nitrate will react with carbon monoxide, acetylene, phosphine, arsine, formaldehyde and hydrogen sulphide.

The presence of carbon monoxide may be shown and estimated quantitatively by means of a test employing pyrogallic and tannic acids. About 250 cc. of the gas (under investigation) is shaken with 2.5 parts diluted guinea-pig blood (1 part blood to 20 of water) in a container. The blood is then run into a small test tube and 0.04 g. of a mixture of equal parts pyrogallic and tannic acids is added. The tube is permitted to stand at least ½ hour after shaking the contents. If the precipitate is gray-brown, carbon monoxide is present in less than 0.01 per cent; if the precipitate is red, the intensity of the color is proportional to the amount of monoxide present.

EFFECT OF ETHYLENE AS AN ANESTHETIC

In connection with the use of an anesthetic, the effect upon the composition and characteristics of the blood must receive some attention. One of the most pronounced features of the blood is its slightly alkaline reaction (*p*H 7.39), which is protected by buffers in the blood plasma. There is present a considerable amount of buffers to protect the blood during heavy exercise when quite large quantities of lactic acid may be formed. The alkali available in the blood for buffering is spoken of as the alkaline reserve. A decrease in this reserve is an acidosis even if the blood still maintains its normal *p*H value. Anesthesia has an effect on the blood which depends upon the substance used as an anesthetic. According to Leake[33] ether and chloroform cause a lowering of the blood *p*H while nitrous oxide and oxygen bring about an initial alkalemia (blood alkalinity) which gradually tends toward an acidemia (blood acidity). The effect of ethylene-oxygen anesthesia depends upon whether or not there is a lack of oxygen in the blood (anoxemia). When there is, the result is said to be practically the same as in nitrous oxide-oxygen anesthesia. Without anoxemia there is a lowering of the *p*H which is not beyond normal limits after 40 minutes of anesthesia.

Oberhelman and Dyniewicz[34] reported that ethylene-oxygen anesthesia caused less decrease in the alkaline reserve than that induced by ether, chloroform or nitrous oxide, and there was no approach to a dangerously low level in any uncomplicated cases. Ethylene-ether apparently had a somewhat greater disturbing action than ethylene-oxygen. It was also noted that the effect on blood sugar was slight.

and no changes which exceeded the normal variation were observed in the non-protein nitrogen content (urea) of the blood. The changes in blood pressure were more similar to those brought about by normal sleep than when anesthesia was induced by ether, chloroform or nitrous oxide.

In tests conducted upon diabetics protected by insulin, Lehmann[35] observed there was no post-operative acidosis in cases where there was a high or low blood sugar level. In fact, the post-operative plasma carbon dioxide value was said not even to approach an acidosis.

A study of the effects produced by ethylene-oxygen anesthesia in normal subjects has been reported by Brumbaugh.[36] Fifteen subjects were anesthetized for 1 hour without premedication and without operative or other complicating factors. No changes were observed in the hemoglobin, icterus index,[37] coagulation time of the blood, character of the blood clot, urine or pulse rate. Slight increases were observed in blood sugar and in the systolic blood pressure. No increase in the blood urea was noticed immediately after anesthesia, but an increase averaging 18.7 per cent was noted 24 hours afterwards. There was a slight but temporary acidosis. Comparable results are given by Trout[38] who found, in addition to the effects on blood sugar and coagulation time which were observed by other workers, that there was only a slight disturbance of the native complement of the blood.[39] In working on dogs which had been held under ethylene anesthesia for 20 minutes, he observed increase in both blood sugar and native complement and decreases in coagulation and bleeding times. The changes, however, were less than when other anesthetics were used.[40]

Another of the effects of various anesthetic gases which has been studied is the change in the osmotic resistance of the erythrocytes (red blood cells) to hypotonic fluids.[41] It was observed that chloroform caused a marked lowering of the resistance of the red blood cells of a dog while carbon dioxide had the reverse effect. There was an apparent increase after 10 minutes of ether anesthesia although the resistance of the red blood cells was much lower than normal after 30 minutes anesthesia. Either nitrous oxide or ethylene with oxygen caused a slight reduction in osmotic resistance, but even after an hour it was not so low as was found for either ether or chloroform. When ethylene was employed without oxygen and after 20 minutes the animal brought to asphyxiation, the osmotic resistance of the red cells was considerably reduced for 0.4 per cent hypotonic Simmel's fluid but only slightly below normal for the higher dilutions (0.6 and 0.7 per cent). Experiments by Niclous and Yovanovitch have shown[42] that from 70 to 80 per cent of the ethylene which is dissolved in the blood during anesthesia is present in the red cells, the remainder being in the plasma. This indicates that ethylene has slightly less affinity for the erythrocytes than chloroform and about as much as ethyl chloride. The relative distribution was observed both during anesthesia *in vivo* and *in vitro*. The total amount of ethylene in the blood depends upon its concentration in the inhaled air. It varies, for example, between 8 and 10 cc. per 100 cc. of blood as the concentration in the inhaled gas ranges between 65 and 77 per cent. When the amount of ethylene is less than 50 per cent of the inhaled gas, there may be a decided increase in the carbon dioxide content of the blood.

[41] When aqueous solutions of lower osmotic pressure than the blood plasma (hypotonic fluids) are permitted to act on the erythrocytes, a part of the latter absorb so much water by diffusion that they rupture. This is known as hemolysis. The reverse process, i.e., shriveling of the red blood cells, takes place in the presence of a solution of higher osmotic pressure than the blood plasma (a hypertonic solution). Solutions which have the same osmotic pressure as the blood are said to be isosmotic or isotonic. C. D. Leake, C. Backus, H. Burch and K. O'Shea, *Proc. Soc. Exptl. Biol. Med.*, 1927, **25**, 92. C. D. Leake, H. Lapp, J. Tenney and R. M. Waters, *ibid.*, 93, 94; *Chem. Abs.*, 1928, **22**, 2616.

Lazarev[43] has found that some narcotics are more soluble in water than in blood and others have reverse solubilities. From this he concludes that some of the narcotic is present in combination with a portion of the blood and is not truly dissolved. The values of the ratio of the bound narcotic to the water-dissolved portion are shown in Table 235.

TABLE 235.—*Ratio of Dissolved to Bound Solute.*

Substance	Ratio	Substance	Ratio
Nitrogen	0.13	Methane	0.5
Nitrous oxide	0.2	Acetylene	0.2 to 0.3
Ethyl chloride	0.8 to 2	Ethylene	0.8 to 1.25
Chloroform	3.3	Benzene	0.8
Diethyl ether	0.2	Cyclohexane	4.4
Pentane	11.	Hexane	22.
Heptane	53.5		

He reported that strong narcotics are probably completely in the bound condition in the blood.

The effect of ethylene on various organs of the body has received some attention. Walton[44] has shown, for example, that varying degrees of ethylene or ether anesthesia for times up to 1 hour had no effect on the 24-hour urinary output. Rosenthal and Bourne[45] observed that when nitrous oxide and ethylene were administered through a mask there was no resultant disturbance of the liver. On the other hand, when given in a closed chamber with poor oxygenation, both immediate and delayed hepatic disorders resulted. The consequences were far more severe when chloroform was used and somewhat more so when ether was administered. In the former case after 30 minutes anesthesia, eight days were required for recovery, while in the latter a day was usually sufficient. The bromosulphalein test[46] showed disturbances of the liver's function for some time after pigment metabolism had returned to normal. The effect of ethylene anesthesia on the stomach was investigated by Johnston and Ivy.[47] They found that gastric secretion was less depressed by ethylene than by ether. Emptying of the stomach by ethylene was delayed through loss of motion or because of closing of the outlet of the stomach by contraction of the pylorus.

PROPENE AND ITS HOMOLOGUES AS ANESTHETICS

One of the earliest reported uses of a hydrocarbon to induce anesthesia is the statement that Snow used amylene on 238 patients in the middle of the nineteenth century.[48] Since that time very few of the alkenes have been so employed to any extent. In 1924, Brown[49] stated that propene possessed anesthetic properties and, in concentrations as low as 37 per cent, when mixed with either oxygen or air was capable of inducing anesthesia. The concentration of hydrocarbon which was necessary to maintain anesthesia was even less and varied from 20 to 31 per cent. It was observed, however, that when the proportion of olefin was above 65 per cent it was more or less poisonous, toxic symptoms appearing in 2 minutes when mixtures containing more than 70 per cent propene were used.

In the following year, Riggs[50] reported the anesthetic actions of the lower members of the alkene series. It was noted that ethylene and propene, unlike butene and pentene (amylene), caused no nervous symptoms or excitement stage. Light anesthesia was induced in white rats of 100 to 150 g. weight in from 15 to 22 minutes by mixtures containing 90, 40, 20 and 6 per cent, respectively, of the successive straight-chain alkenes from ethylene to pentene. As a result, the potencies of the gases were given as ethylene, 1, propene, 2.25, butene, 4.5 and pentene, 15. It was found that death, when it occurred, resulted from respiratory failure, although it was believed that butene and pentene might have some action on the heart.[51] This latter observation was made more frequently with propene which had been stored for some time than with freshly prepared, uncompressed gas.[52] In some cases, where a mixture of 40 to 50 per cent propene, 20 per cent oxygen and 40 to 30 per cent nitrogen was employed, there was a muscular rigidity which was accompanied by contraction of the oculomotor muscles and resulted in a stare. Electrocardiographic studies on men showed that there was a slowing of the pulse rate during propene anesthesia which returned to normal shortly after the anesthetic was withheld. The lethal dose of propene is said to be about 2/3 more than the anesthetic concentration.[53] The respiratory center of dogs and cats is stated to be stimulated by a narcotic concentration of propene but paralyzed by a lethal one. In cats, dogs and mice, propene seemed to excite some portion of the motor tracts. There was said to be some substance in the propene which was similar in reactions to it, but more powerful pharmacologically.[54]

The results which were obtained by electrocardiographic methods on animals by Riggs and Goulden[55] have been obtained in the same manner for man by Kahn and Riggs.[56] They observed that complete anesthesia occurred on the average after eight inhalations. There was no particular effect on the heart except during complete narcosis. The memory of the patient returned very rapidly after removal of the anesthetic.

ACETYLENE AS AN ANESTHETIC

In 1923 Gauss and Wieland[57] reported that acetylene from which toxic substances such as phosphine had been removed was an effective anesthetic. The gas was said to have a characteristic, not unpleasant odor and a bitter taste. Using an especially designed machine for the administration, anesthesia was initiated with a mixture containing 60 per cent of acetylene and 40 per cent of oxygen. After 1 minute the hydrocarbon was increased to 70 per cent and then reduced to 60 per cent at the end of another minute. The proportion of acetylene was then diminished until the minimum necessary to maintain anesthesia was reached, usually between 25 and 40 per cent. In 75 per cent of the cases tried, anesthesia was complete after 2 minutes, the duration varying under different requirements between 3 and 136 minutes. There was only occasionally a state of excitement before complete narcosis. No deleterious effects on the body functions were observed. Although recovery was sometimes accompanied by nausea and vomiting for short periods, consciousness returned very shortly after removing the mask.

Rimarski[58] has studied the explosiveness of mixtures of acetylene and air but concluded that there is little danger on this score from its use in anesthesia. He found that, whereas 3.35 per cent was necessary for any explosion, the proportion in most parts of the room was very small and near the patient was only about 1 per cent. The precaution of keeping any hot apparatus or any sources of electric sparks at a distance from the patient was believed to prevent any possibility of a disaster. There appeared to be very little removal of acetylene in breathing, and there was only 1.7 per cent of carbon dioxide in the expired air.

The opposition to acetylene, aside from its inflammability, has been either on the grounds of its odor and irritant action[59] or upon the difficulty of removing acetone vapors from acetylene which has been shipped in a cylinder containing that substance.[60] This latter difficulty has been overcome by Reiber[61] who removed the ketone by passing the gas over an adsorbent such as activated carbon.

According to Heymans and Bouckaert[62] acetylene is less toxic than either chloroform or ether, and it has a different effect on the respiratory center, viz., rather than depressing, it stimulates. A mixture of 80 parts acetylene and 20 of oxygen is said to bring about complete narcosis and muscular relaxation in 2 to 3 minutes. Moreover, acetylene may be used together with nitrous oxide and oxygen, and thus the normal oxygen concentration of the arterial blood is maintained, a desirable effect which cannot be secured when nitrous oxide and oxygen are used alone.

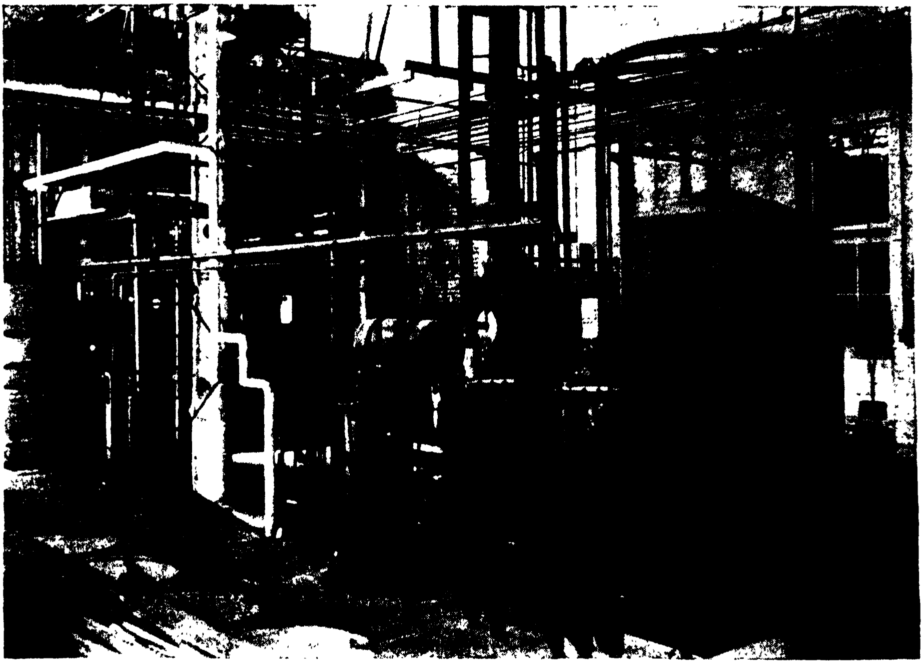
CYCLOPROPANE IN ANESTHESIA

In studying the effect of propene on dogs and cats by means of the electrocardiograph, Caine and Reynolds[63] observed certain cardiac irregularities which disappeared on reducing the concentration of gas and were thought to be caused by some impurity in the gas. These irregularities were not observed in ether, nitrous oxide, ethylene or acetylene. Subsequently, Lucas and Henderson[64] investigated cyclopropane as the possible cause of the irregularities observed by Caine and Reynolds and found not only that this gas was not responsible, but that it was a good anesthetic, from 10 to 12 per cent being sufficient to produce surgical anesthesia in cats.



Courtesy Industrial and Engineering Chemistry

FIG. 313.—Chlorination Unit Employed in **Synthesis** of Cyclopropane. (See Chapter 30) (H. B. Hass, E. T. McBee, G. E. Hinds and E. W. Gluesenkamp)

Cyclopropane has a sweetish odor, like ethylene and chloroform, and is not difficult to breathe.[65] The principal effect observed when it was used on a dog for 1½ hours was a slight drop in blood pressure. Respiratory volume was good, and alkaline reserve and the blood acidity were affected only slightly even on prolonged anesthesia. Cyclohexane was also studied as a possible anesthetic,[66] and was found to cause few or no symptoms of irritation; from these the animals recovered completely. Cyclohexane was 4.8 times as powerful an anesthetic as cyclopropane and 3.2 times as potent for fatal concentrations.

Waters and Schmidt[67] have reported the results of the use of cyclopropane in a large number of cases where anesthesia was desired. Premedication was effected by the hyperdermic injection of from 1/8 to 1/4 grain of morphine (0.008 to 0.016 g.) and from 1/200 to 1/100 grain of scopolamine (0.00032 to 0.00065 g.) about 1½ hours before anesthesia. Anesthesia was carried out using various proportions of cyclopropane up to about 43 per cent, which was the average amount necessary to cause respiratory arrest. It was observed that the oxygen content of the gas must be kept well above 20 per cent. A comparison of the fatalities in regard to time and cause is given in Table 236.

TABLE 236.—*Comparison of Fatalities Resulting After Anesthesia.*

	Extra-Abdominal Cases			Abdominal Cases	
	Ether	Cyclopropane	Ethylene	Ether	Cyclopropane

Carcinoma	3	4	4	5	4
Shock	0	0	0	1	1
Others	3	2	2	1	2

The results show that there was less tendency toward respiratory troubles when cyclopropane was employed as an anesthetic than when either ethylene or ether was used, but there was a somewhat greater tendency toward circulatory complications. The non-fatal cases are compared graphically as to complications in Figs. 314 and 314A. Cyclopropane does cause some nausea but less emesis (vomiting) than the other anesthetics studied. Pathological changes were found in the heart after necrotomy in some instances, but they could not be conclusively ascribed to the cyclopropane.

Because of the non-irritant properties of this same gas, there was no tendency to laryngospasm, the normal protection from extreme dosage of a gas, and some trouble was experienced in passing gradually between the different degrees of narcosis. The most valuable sign which can be used to indicate the approach of the limit of tolerance is a change in the character of the pulse, such as arrhythmia or an acceleration or deceleration in rate. In fact, Waters[68] has stated that the appearance of extreme irregularities of the heart should be met by a marked reduction in the concentration of cyclopropane in the gas mixture. Seevers, DeFazio and Evans[69] investigated the rate at which cyclopropane and ethylene are absorbed and expelled by the body.[70] They found that the former was more rapid in its activity. The carbon dioxide tension of the tissues was also higher during cyclopropane anesthesia.

FIG. 314.—Post-operative Complications Following Anesthesia with Ether, Cyclopropane and Ethylene in Extra-abdominal Surgery. (R. M. Waters and E. R. Schmidt)

Graph represents percentage incidence of each complication following 600 cases for each anesthetic. Table lists percentage showing no complications.

In anesthetizing a dog the action of cyclopropane is said to lie between ether and ethylene in regard to induction, maintenance and recovery from anesthesia. No immediate untoward effects were observed even after narcosis had been prolonged for a considerable time.[71] Without premedication about 25 per cent cyclopropane was sufficient for anesthesia. This hydrocarbon was found to affect the heart during artificial respiration when administered in considerable amount.

Because of the quiet breathing of the patient during cyclopropane anesthesia, it has been found a useful agent in thoracic surgery,[72] and it has been employed in obstetrics.[73] Its explosiveness, however, necessitates the use of a special technique. The results obtained in 2200 cases in which cyclopropane was used have been compared by Schmidt and Waters[74] with a like number in which other agents were employed. In these data deaths which resulted from all causes are included as shown in Table 237.

Graph shows percentage incidence of each complication following 400 cases for each anesthetic. Table gives percentage resulting in no complications.

A certain amount of study has been made upon the influence of cyclopropane on the functions of the body. Taylor and Waters[75] found that there is a leucocytosis which occurs after anesthesia whether induced by ether, nitrous oxide, ethylene or cyclopropane. This reaches a maximum about 4 to 8 hours after operation and

continues for 2 or 3 days. Robbins[76] has observed that anesthetics such as ethylene and cyclopropane cause a cessation of salivary flow by depressing the secretory center.

Peoples and Phatak[77] have investigated the effect of cyclopropane on rabbit's intestine suspended in Locke's solution.[78] A mixture of the hydrocarbon and oxygen such as would be used in anesthesia (10 to 25 per cent cyclopropane) is bubbled through the solution. In the cases observed there was an increase in the tone of the muscles of the intestine and decrease in the amplitude of contraction. The stimulation was proportional to the concentration and reached a maximum for 25 per cent cyclopropane. From these results, Peoples and Phatak believed that there should be less tendency toward post-operative intestinal stasis and the resulting distension when cyclopropane is used as an anesthetic. In this connection Waters[79] states that work of Meek on dogs has shown that deep cyclopropane anesthesia either averts or inhibits both contraction and propulsion phenomena of the intestine. Prompt return to normal, or greater than normal (6 out of 14 cases) occurred after removal of the wash.

The effect of cyclopropane on the heart and circulatory system has been intimated previously. Waters[80] has found that intravenous injection of epinephrine in a dog under light chloroform anesthesia will frequently precipitate ventricular fibrillations[81] but does not do so under light cyclopropane anesthesia.

[81] Ventricular fibrillations are the independent, as opposed to co-ordinated, contractions of the muscle fibres of the ventricles. The result is usually fatal, and is said not to have been observed electrocardiographically in man for this reason.

Chapter 54

Thermodynamics and Its Application to Petroleum Technology

The application of thermodynamic principles to the field of petroleum technology has been made possible through the innumerable investigations of a vast number of contributors. Although LeChatelier[1] had pointed out the importance of a knowledge of chemical equilibria in industrial chemistry as early as 1888, for over a period of approximately 35 years relatively little work was conducted along the lines of research in this field. Perhaps the former widespread prejudice against any practical use of chemical thermodynamics was not without foundation, as Lewis and Randall[2] have stated in their critical review of this science. The correlation of the exact laws of thermodynamics with poorly founded or even erroneous assumptions cannot be expected to give representative predictions. In addition, there was a further disadvantage, especially in the organic field, in the almost total lack of adequate accurate thermal data. Determinations along these lines since about 1925 have, however, furnished a basis for the introduction of this science into the widespread field of the petroleum industry.

The value of numerous thermodynamic concepts, such as enthalpy, entropy, fugacity and free energy, is rapidly becoming recognized not only in scientific investigations but also in commercial enterprises. For these reasons a general discussion of such topics, especially in regard to their practical application, has been incorporated in this chapter. However, it should be stressed that in many instances the values given are by no means absolute or final. Subsequent revision of these quantities may be expected as a direct result of refinements in experimental technique, elimination of observational errors and recalculations in view of later and more exact fundamental data. Yet variations of this type have not been uncommon in the other fields of chemistry of longer standing, and so these changes may be expected to occur in an analogous manner. The free energy values are typical examples of data falling into this class. However, the reasons for these deviations will be considered and explained in the following pages.

CHEMICAL THERMODYNAMICS

The work of Lewis and Randall[3] contributed largely to the establishment of thermodynamics in general chemistry. However, their study was devoted almost exclusively to inorganic chemistry as the prerequisite organic data were almost entirely lacking at that time (1923). The systematic researches of Parks and his collaborators, together with the observations of numerous other investigators, greatly enhanced the literature pertaining to the field of organic compounds. In 1932, the latter efforts were culminated, critically evaluated and embodied into a concise volume by Parks and Huffman.[4] Over 300 free energy values representing hydrocarbons, alcohols, phenols, acids, halides and organic compounds of oxygen, sulphur and nitrogen were included in this text. These results, according to Parks,[5] although merely preliminary and semi-quantitative, serve as an initial foundation for "thermodynamic organic chemistry." "Moreover, at the present time," Parks continues, "new free energies and more accurate ones are being added to the literature at an accelerated pace."

---

[3] G. N. Lewis and M. Randall, *loc. cit.*

Before discussing free energy and the application of this quantity to industrial problems, it is necessary to review a few of the relations and definitions involved.[6]

The Concept of Free Energy

Although free energy may be expressed quite simply in a mathematical sense (as will be shown shortly), this concept does not lend itself to a thorough verbal description. A rigorous derivation, such as that of Gibbs[7] and others, derived from a scientific and mathematical basis, is tedious and involved. However, Francis and Kleinschmidt[8] have employed a simple analogy which may help to explain the meaning of free energy.

These authorities consider as an example the flow of water in a system composed of two reservoirs, *A* and *B*, joined by a pipe. By measuring the height of the water levels in both *A* and *B* from some arbitrary datum plane (or in other words, the "head" or "gravitational potential"), the respective tendency of the water to flow from one to the other can be ascertained. In addition, it will be noted that the difference between the heights of the water levels in the two reservoirs is a measure of the work that could be done, theoretically, in allowing a given mass of water to flow through a turbine or other device in going from the higher reservoir to the lower. From this example, Francis and Kleinschmidt define "gravitational potential" either as the tendency of the material (that is, the water) to change its position, or as the available work that could be performed by allowing a unit quantity of material to change its position. Gibbs and others have shown that there exists a property of matter which bears essentially the same relation to chemical change that the "head" or "gravitational potential" has to the flow of water. In the nomenclature of Gibbs, this property is known as the "thermodynamic potential," in a sense analogous to that used above for the gravitational potential. Lewis[9] prefers to refer to this quantity as "free energy." "Available energy" is another synonym that has been suggested. However, of the three terms, Lewis' "free energy" is the one that has become most generally accepted.

Thus, from the above discussion, it will be seen that the change in free energy may be regarded as the driving force of a reaction, or the high-grade energy that would be made available during the transformation. Briefly then, if a large quantity of high-grade energy is liberated during a change, the reaction is thermodynamically possible and spontaneous. If, however, the transformation involves the passage from a state of lower to higher free energy levels, the latter can only be accomplished by the addition of energy, as, for instance, mechanically (by compression), electrically (by electrolysis or ionization) or thermally, just as in the case of the water analogy, where in order to increase the gravitational potential it is necessary to use a pump.

[6] A thorough discourse on thermodynamics cannot be included in this text. Reference should be made to G. N. Lewis and M. Randall, "Thermodynamics," McGraw-Hill Book Co., Inc., New York and London, **1923**. H. S. Taylor, "Treatise on Physical Chemistry," D. Van Nostrand Co., Inc., New York (Second Edition), **1930**, Chapter 2. Also J. H. Perry, "Chemical Engineers' Handbook," McGraw-Hill Book Co., Inc., New York and London, **1934**, Chapter 5.

[7] In this connection, see W. R. Longley and R. G. Van Name, "The Collected Works of J. Willard Gibbs," Longmans, Green and Co., New York, 1928, **1**, **87**.

[8] A. W. Francis and R. V. Kleinschmidt, *Oil and Gas J.*, 1929, **28** (29), 118; *Chem. Abs.*, 1930, **24**, 2369.

[9] G. N. Lewis and M. Randall, *loc. cit.*

However, for the actual occurrence of a reaction to an appreciable extent, the fulfillment of the free energy requirements is a necessary but not a sufficient condition. Rates of reaction must also be considered in answering this question. Francis and Kleinschmidt[10] carry their water analogy one step further, and compare the pipe line joining the reservoirs to a catalyst for a chemical reaction. When the main connecting the two bodies is large, the rate at which the water flows from the higher to the lower level is quite rapid, and conversely, when the pipe is small, the rate will be slower. Thus, the pipes with their different rates of flow may be regarded as catalysts, since the latter have the property of affecting the speed of chemical transformations. It should be borne in mind, however, that no pipe exists which can cause the water to flow from a lower to a higher level without the application of external work. The same principle is true of catalysts, namely: A reaction that is thermodynamically unfeasible (i.e., one in which the free energy change is from a lower to a higher level) cannot be forced to proceed by means of catalysts. In this respect, Francis and Kleinschmidt point out the dual role played by temperature. The addition of energy, in the form of heat, directly affects the free energy (as will be shown later in this chapter), so that reaction which might be impossible thermodynamically at one temperature may become possible at another. Furthermore, high temperatures tend to break down chemical inertness or resistance to change, and allow changes to proceed at greater speeds.

THERMODYNAMIC NOMENCLATURE

Since free energy calculations are used primarily in scientific rather than technical operations, it is customary to employ the metric rather than the British system of units. The thermodynamic variables in most general application, together with their symbols and units, are listed below:

	Symbol	Units
Volume	V	Liters
Temperature (absolute)	T	°K. (°K. = °C. + 273.1)
Pressure	P	Atmospheres
Heat (general)	q	Cal.
Heat capacity	C	Cal./°K./g. (or mole)
Heat content	H	Cal.
Internal energy	U	Cal.
Entropy	S	Cal./°K.
Free energy	F	Cal.
Work content	A	Cal.

Of the variables given above, temperature, pressure and heat capacity are termed "intensive properties," that is, they are independent of the quantity of material.[11] The others included are "extensive" and are proportional to the mass of the substance involved. However, it is convenient to compare these functions on a molar basis, for instance, volume per mole and entropy per mole, so that in this case molal entropy[12] or molal volume are intensive quantities, that is, are independent of the amount of material taken.

---

[10] A. W. Francis and R. V. Kleinschmidt, *loc. cit.*

[11] Consult G. N. Lewis and M. Randall (*loc. cit.*) for a discussion of intensive and extensive properties.

[12] Molal entropy is generally measured in terms of "entropy units" (abbreviated as E.U.) and has the dimensions of calories per degree absolute per mole.

As to the general meaning of the above-mentioned terms, volume, temperature and pressure are in common use and require no further explanation. The symbol q is used to designate any quantity of heat, in general. H represents the heat content of a system, while U is the internal energy, or the actual energy content of the material under consideration. These quantities are related thermodynamically by the equation

$$H = U + PV$$

Similarly, F, the free energy or chemical potential and A, the work content, can be expressed as

$$F = A + PV$$

(The significance of these terms will be seen more clearly in the discussion given in the following section.) The entropy, S, is a quantity, which like free energy does not permit a rigorous verbal description, but it will suffice to say it is a measure of the waste thermal energy in a system. For a reversible process, an infinitesimal increase in entropy is related to the general heat term, q, by the differential equation:

$$dS = \frac{dq}{T}$$

where dq represents an infinitesimal amount of heat absorbed. A finite change in entropy, designated by ΔS, is given by

$$\Delta S = \frac{q}{T}$$

The heat capacity, C, is a very useful function and is governed by the differential equation

$$C = \frac{dq}{dT}$$

where dq and dT represent infinitesimal increments in the heat quantity and absolute temperature, respectively. The heat capacity is generally designated as C_p for a system maintained at constant pressure or C_v for one maintained at constant volume. Mathematically, the latter quantities are:

$$C_p = \left[\frac{\delta H}{\delta T}\right]_p$$

$$C_v = \left[\frac{\delta U}{\delta T}\right]_v$$

which, stated in words, are: The heat capacity at constant pressure is equal to the rate of change of the heat function with respect to temperature at constant pressure, and the heat capacity at constant volume is equal to the rate of change of internal energy with respect to temperature at constant volume. The heat capacity is also related to the change in entropy

$$\frac{dS}{dT} = \frac{C}{T}$$

or

$$dS = C\, d\ln T$$

These relations are only a few of the many possible thermodynamic equations. There are several that require a more detailed consideration, and, therefore, the more important of these will now be discussed.

Relationship between Change in Heat Content and Change in Free Energy

The change in heat content (ΔH) and the change in free energy (ΔF) are in almost constant use in thermodynamic calculations. Although in a few instances these two quantities may be very nearly equal numerically, this is by no means the general case. The differentiation between these two quantities has been discussed by Parks and Huffman[13] and will be shown below.

Consider a simple system (such as a group of reacting molecules) which may be represented in its initial state by the subscript A, undergoing a transposition to some reproducible state B. Furthermore, suppose that this transformation occurs at constant temperature and pressure and in such a manner that no work is involved except that which is necessary to maintain the conditions of constant pressure. The increase in a thermodynamic variable (such as heat content, free energy, volume and so forth, represented by the general symbol X) will be given by:[14]

$$\Delta X = X_B - X_A \quad \text{or} \quad -\Delta X = X_A - X_B$$

In the case of the heat content, H (or heat function, as it is sometimes called), $\Delta H = H_B - H_A$ and is the heat absorbed by the system under these conditions. Likewise, $-\Delta H$ will represent heat evolved. From the first law of thermodynamics, ΔH is related to the increase in internal energy,[15] ΔU, and the change in the pressure-volume product, $\Delta(PV)$, by the relation:

$$\Delta H = \Delta U + \Delta(PV)$$

Since this reaction was assumed to take place at constant pressure,

$$\Delta H = \Delta U + P\Delta V$$

If the change in volume is positive (i.e., V_B is greater than V_A), the $P\Delta V$ term represents the work done by the system on the surroundings. On the other hand, if the transformation is accompanied by a decrease in volume, the above term is a measure of the work done upon the system by the surroundings. In either case the work involved is not considered available for useful purposes.

Although the change in the intrinsic energy, ΔU, is of a more fundamental nature than the change in heat content, the latter quantity is of more practical importance to the chemist since most processes take place at constant pressure. Thus, if heat is evolved in the above transformation, there will be a decrease in the heat content, and the heat evolved ($-\Delta H$) is the heat of reaction, as determined in a constant-pressure calorimeter. In other words, $-\Delta H$ is symbolic of the useful energy (measured as heat) available in a reaction carried out at constant pressure and temperature.

The maximum work ($-\Delta A$) obtainable from the system is another thermodynamic variable. Under the assumed condition of constant pressure, however, $-\Delta A$ does not represent the actual work available for useful purposes, since as mentioned previously, a certain amount of work, $P\Delta V$, is usually necessary to maintain the conditions of constant pressure. Subtracting the latter from the value of the maximum work, the decrease in free energy is obtained:

$$-\Delta F = -\Delta A = P\Delta V$$

---

[13] G. S. Parks and H. M. Huffman, *loc. cit.*

[14] Using the calculus notation, a finite change in a thermodynamic variable, such as X, is usually designated as ΔX (the difference between the values of that quantity in the final and initial states). Similarly, dX represents an infinitesimal increment. It should be noted that these changes may be either positive or negative.

[15] This quantity is also known as the energy content, or intrinsic energy. G. N. Lewis and M. Randall (*loc. cit.*) use the symbol ΔE to represent this variable.

It will be seen, therefore, that $-\Delta F$ represents the maximum amount of useful work that can be obtained from a reaction occurring at constant temperature and pressure.[16]

The free energy is related to the heat content and entropy[17] by the fundamental thermodynamic equation:

$$F = H - TS$$

or for an isothermal process conducted at constant pressure,

$$\Delta F = \Delta H - T\Delta S$$

where T is the absolute temperature, S is the entropy, and ΔS is the increase in entropy in the system and is the difference between the entropy value for the product and that associated with the reactants. (ΔS is a measure of the degree of irreversibility of a reaction or degradation of the system as a whole.) Parks and Huffman suggest transposing the latter equation to give:

$$-\Delta H = -\Delta F - T\Delta S$$

Here the term $-\Delta H$ represents the total decrease in useful energy during the process, $-\Delta F$ is the decrease in useful energy convertible to work and $-T\Delta S$ is the decrease in unavailable energy (heat that cannot be converted into useful work[18] at constant temperature and pressure).

THE SIGNIFICANCE OF ΔF

The importance of the change in free energy in determining the direction of a chemical reaction has been stressed by Parks and Huffman. Thus, in the previous case, assuming a reaction to take place at constant temperature and pressure, if ΔF has a large negative value, the transformation may occur spontaneously. If ΔF is positive (indicating a positive increment in the variation of free energy), reaction will proceed to an appreciable extent only through the application of external work or energy. On the other hand, when $\Delta F = 0$, a state of equilibrium exists, and no further change is to be expected.

In the case of the formation of one mole of water from its elements at 25°C. and one atmosphere pressure, the change in free energy is given by the reaction:

$$H_{2(g)} + \tfrac{1}{2}O_{2(g)} = H_2O_{(l)};\ \Delta F^{\circ}_{298} = -56{,}560 \text{ cal.}$$

In actuality, after this reaction is once initiated, it proceeds quite vigorously to completion. The reverse of the above equation, i.e., the decomposition of water into its elements at 25°C. can only be accomplished by a process such as electrolysis. Transformations involving a change of state, such as the conversion of ice to water at 0°C. or water to steam at 100°C. and atmospheric pressure, are examples of equilibrium reactions and are accompanied by no change in ΔF at the respective temperatures.

Since the free energy change indicates the degree of completion of a reaction, by means of the thermodynamic relationship,

$$\Delta F^{\circ}_{T} = -RT \ln K$$

---

[16] It will be noted that H bears the same relation to U as F bears to A. Thus, $H = U + PV$ and $F = A + PV$ However, since most reactions are carried out at constant pressure rather than at constant volume, C_p, H and F are in much more general use than the corresponding C_v, U and A.

[17] The entropy may be considered as a measure of the waste thermal energy, that is, energy not available for conversion into mechanical work.

[18] The term "useful work" as used here does not include work expended in maintaining the system at constant pressure.

where R is the gas constant, T is the absolute temperature (°K), it is possible to obtain the equilibrium constant, K, for the reaction. Furthermore, from the latter value it is possible to calculate the actual equilibrium pressures or concentrations which should be present in the system under equilibrium conditions.

It should be noted, however, that whereas ΔF is indicative of the direction and extent of a chemical reaction, yet no information as to the time necessary to reach this state of equilibrium may be obtained from these data. Parks and Huffman discuss this serious limitation of thermodynamics. Thus, in the case of the formation of liquid water from its elements at 25°C., in the absence of a catalyst or a starting mechanism (such as an electric spark), the reaction velocity is extremely slow due to the low reactivity of the substances involved. However, as the above authorities state, this property of chemical inertness, although frequently a serious handicap, is oftentimes a decided advantage. For instance, it makes possible the existence of many compounds (such as benzene) which from the viewpoint of thermodynamics are unstable with respect to decomposition to their constituent elements.

EVALUATION OF ΔF

Unfortunately, there is no manner in which ΔF can be measured directly, as for instance, can be done with heats of combustion and heats of reaction. However, the free energy change in a reaction can be readily calculated from experimental data. In general, four methods are available, namely:

(1) From equilibrium data and measurements of the equilibrium constant, according to the relation

$$\Delta F^{\circ}_{T} = -RT \ln K$$

(2) From data obtained with an electric cell, involving the reaction in question. By measurement of the reversible electromotive force, E, the increase in free energy may be obtained from the formula

$$\Delta F = -N\mathbf{F}E$$

where N is the number of chemical equivalents involved in the transformation and **F** is Faraday's equivalent.[19]

(3) From the fundamental thermodynamic equation defining free energy, discussed previously,

$$\Delta F = \Delta H - T\Delta S$$

(4) From a combination of chemical reactions, for which the corresponding free energy values are known, to give the desired reaction.

However, each of these are subject to definite restrictions and inherent errors, due to many factors.

The first method may be used when the necessary equilibrium data are available at one or more temperatures.[20] However, Parks[21] has stated that such studies are naturally limited to interactions which are not unduly complicated by side reactions. Furthermore, the quantities of reactants and products existing under equilibrium conditions must be sufficiently large to measure without introducing appreciable errors. However, with moderate accuracy in the determination of K, the free energy values are usually quite satisfactory, a 10 per cent error in the equilibrium constant at 500°K. (227°C.) involving an error of only 90 cal. in ΔF°_{500}, according to Parks and Huffman.[22] Parks points out the fact that by the use of specific catalysts and improvements in analytical technique, this method may eventually become more extensive in applicability.

---

[19] The values usually employed for this constant are: **F** = 96,500 coulombs per equivalent or 23,068 cal. per volt equivalent.

[20] For example, see R. N. Pease and E. S. Durgan (*J.A.C.S.*, 1928, **50**, 2715; *Chem. Abs.*, 1928, **22**, 4459; *Brit. Chem. Abs.* **A**, 1928, 1324) and F. E. Frey and W. F. Huppke (*Ind. Eng. Chem.*, 1933, **25**, 54; *Brit. Chem. Abs.* **A**, 1933, 227; *Chem. Abs.*, 1933, **27**, 654). Also G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, 1932.

[21] G. S. Parks, *Ind. Eng. Chem.*, 1933, **25**, 887; *Chem. Abs.*, 1933, **27**, 4473; *Brit. Chem. Abs.* **A**, 1933, 1014.

The electromotive force measurement method permits a very accurate estimation of free energy values. Unfortunately, its usefulness with respect to organic reactions is almost completely confined to certain simple oxidation-reduction mechanisms.[23]

The use of the third method, which is the most general one, involves an application of the third law of thermodynamics.[24] In order to obtain ΔS, however, an extensive knowledge of thermal data is required. Such data were almost completely lacking prior to about 1925. From low-temperature specific heat observations, the entropy may be calculated quite readily. In some cases, ΔH can be obtained by direct measurement of the heat of reaction by usual calorimetric procedures. Usually, this quantity must be evaluated indirectly from heats of combustion of the various substances involved by the application of Hess' law.[25] The use of such data may lead to a considerable error, since the major portion of the available combustion data was obtained in the early thermochemical studies and is subject to some uncertainty.[26] Much later determinations[27] on heats of combustion are providing more reliable values. However, Parks and Huffman have stated that although that procedure is the simplest and most convenient method, in most cases it cannot yield satisfactory results with respect to free energy values until the heat of combustion of the compounds involved are measured to within 0.02 or 0.03 per cent. According to these authorities, this accuracy is by no means impossible with the calorific facilities now available and with reasonable technique.

The fourth method involves the combination of various chemical equations and their corresponding free energies to give the desired reaction and its free energy value, as indicated by the equation:

$$A + B = C;\ \Delta F^\circ = \Delta F_C^\circ - (\Delta F_A^\circ + \Delta F_B^\circ)$$

where ΔF° is the free energy of reaction, and ΔF_A°, ΔF_B° and ΔF_C° represent the free energies of formation of substances *A*, *B* and *C*, respectively. Of course, the accuracy of the result in this case is directly dependent upon the accuracy of the other free energy values, since the errors involved are directly accumulative.

---

[22] G. S. Parks and H. M. Huffman, *loc. cit.*

[23] One of the present applications is the conversion of hydroquinone to quinone, as investigated by J. B. Conant and L. F. Fieser, *J.A.C.S.*, 1923, **45**, 2194; *Chem. Abs.*, 1923, **17**, 3866; *J.C.S.*, 1923, **124** (2), 727 and E. Schreiner, *Z. physik. Chem.*, 1925, **117**, 57; *J.C.S.*, 1925, **128** (2), 978; *Chem. Abs.*, 1926, **20**, 6. See also G. S. Parks and H. M. Huffman, *loc. cit.*

[24] According to G. N. Lewis and G. E. Gibson, *J.A.C.S.*, 1920, **42**, 1528; *Chem. Abs.*, 1920, **14**, 2880; *J.C.S.*, 1920, **118** (2), 585: "If the entropy of each element in some crystalline form be taken as zero at the absolute zero, the entropy of any pure crystal at the absolute zero is zero, and the entropy of any other substance is greater than zero." Most authorities agree that this is the most satisfactory statement of the third law of thermodynamics. See E. D. Eastman, *Chem. Rev.*, 1936, **18**, 257; *Chem. Abs.*, 1936, **30**, 5112, for a discussion of the third law.

[25] See A. L. Marshall, "Thermochemistry," in H. S. Taylor, "A Treatise on Physical Chemistry," D. Van Nostrand Co., Inc., New York, **1930**, 285.

[26] In this connection it should be noted that G. S. Parks and H. M. Huffman (*loc. cit.*) have stated that many of the combustion values as given in the International Critical Tables (McGraw-Hill Book Co., Inc., 1929, **5**, 162) are in error from 1000 to even over 3000 cal. Although this represents, in general, a percentage error of about 0.1 per cent in the heat of combustion value, it has a much more appreciable effect on the heat of reaction and consequently the free energy, due to the loss of significant figures by subtraction.

[27] In this respect, consult F. D. Rossini, *Bur. Standards J. Research*, 1931, **6**, 37; 1932, **8**, 119; 1934, **13**, 21; *Chem. Abs.*, 1931, **25**, 1727; 1932, **26**, 2109; 1934, **28**, 6065; *Brit. Chem. Abs.* **A**, 1931, 433; 1932, 341; 1934, 1071. G. B. Kistiakowsky, H. Romeyn, Jr., J. R. Ruhoff, H. A. Smith and W. E. Vaughan, *J.A.C.S.*, 1935, **57**, 65; *Brit. Chem. Abs.* **A**, 1935, 304; *J. Inst. Pet. Tech.*, 1935, **21**, 89A; *Chem. Abs.*, 1935, **29**, 2065. G. B. Kistiakowsky, J. R. Ruhoff, H. A. Smith and W. E. Vaughan, *J.A.C.S.*, 1935, **57**, 876; *Chem. Abs.*, 1935, **29**, 4254; *Brit. Chem. Abs.* **A**, 1936, 825; *J. Inst. Pet. Tech.*, 1935, **21**, 255A. See also W. A. Roth et al. in H. Landolt and R. Börnstein, "Physikalisch-chemische Tabellen," 5th Edition, revised by W. A. Roth and K. Scheel, J. Springer, Berlin, **1931**.

FREE ENERGY OF FORMATION

From a table of free energies of formation for various substances, the increase in free energy in a reaction may be calculated, as indicated in method (4) given above. However, since the numerical value of these quantities varies considerably with the temperature, it is necessary to establish certain definite conditions in order that they may be comparable. For these reasons, each element is taken in a standard reference state[28] which usually is its most stable form at room temperature and 1 atmosphere pressure.[29]

In accordance with these conditions, the free energy of formation of a compound is the change in the free energy value when one mole of the substance is formed isothermally in its standard state at 1 atmosphere pressure from its constituent elements. As a matter of convenience, these values, commonly called "free energies," are usually calculated at 25°C. (298.1°K.) and are designated as ΔF°_{298}. The free energies of the various elements in their respective standard states are arbitrarily taken as zero.

According to Parks and Huffman[30] there are relatively few instances in which the first method given previously for the determination of free energy (involving the equilibrium constant) may be used. One exception to this is the synthesis of methane from carbon and hydrogen at 1400°K. (1127°C.). By means of catalysts such as nickel, cobalt, iron or platinum this reaction may be carried out at 600°K. (327°C.).[31] However, due to inaccuracies in thermal data, especially high-temperature specific heats, and difficulties in determining the equilibrium constant, extrapolation of the free energy values obtained at the high temperatures to 25°C. may introduce serious errors. Therefore, the only other available method, that involving the third law, is generally employed for evaluating the free energy of hydrocarbons.

The standard free energy of formation is represented by

$$\Delta F^\circ_{298} = \Delta H^\circ_{298} - T\Delta S^\circ_{298}$$

where ΔH°_{298} is the heat of formation (change in heat content for the process of formation), ΔS°_{298} is the increase in entropy (the difference between the absolute entropy of the hydrocarbon and that associated with the requisite number of atoms of carbon and hydrogen) and *T* is the absolute temperature (298.1°K.). The heat of formation may be obtained from tables or calculated from heats of combustion values. The increase in entropy, however, must be calculated from molal entropies, which may be evaluated from low-temperature instantaneous heat capacities and thermal data pertaining to changes of state, using the method introduced by Nernst.[32] Thus, if the entropy at 0°K. (— 273.1°C.), S_O, may be taken as zero for a pure, perfectly crystalline substance, then the molal entropy at 25°C. is given by:

---

[28] The standard states are gas, liquid and solid, and are indicated by the subscripts (g), (l) and (s), respectively. In any reaction, it is important that the states be given, as, for example, thermodynamically butane may be considered in the standard state as a liquid (for comparative purposes), although in reality under the conditions chosen to designate the standard state (25°C. and 1 atmosphere) this is impossible. Thus, the standard state of carbon is taken as β-graphite, whereas sulphur is considered to be in the rhombic form under these conditions. Hydrogen, nitrogen and oxygen are referred to as diatomic gases (H_2, N_2 and O_2, respectively).

[29] The symbol X° refers to any thermodynamic quantity corresponding to a standard state. Thus, ΔH° is the "standard change in heat content." However, it is customary to denote the absolute temperature at which this quantity is determined by a subscript. As an example, the standard heat of formation of a compound at 25°C. (298.1°K.) is ΔH°_{298}, whereas at 150°C. (423.1°K.) it would be expressed as ΔH°_{423} and, in general, at T°K., as ΔH°_T.

[30] G. S. Parks and H. M. Huffman, *loc. cit.*

[31] See Carleton Ellis, "The Chemistry of Petroleum Derivatives." The Chemical Catalog Co., Inc., New York, 1934, 105.

$$S_{298} = \int_{T=0}^{T=298} \frac{dq}{T}$$

where dq is an infinitesimal amount of heat absorbed.[33] This method has been applied to over 120 organic compounds by Parks and his collaborators.[34]

The free energy values of the hydrocarbons have been investigated more thoroughly than those of any other class of organic compounds. One reason for this is that the former substances naturally fall into homologous series in which not only the usual physical properties but also certain thermodynamic properties show regularities that are quite pronounced.

Normal Paraffins. In Table 238 are listed the standard free energies of formation of 8 normal paraffins from their elements at 298.1°K. (25°C.) and 1 atmosphere pressure. Also included in this table are the molal entropy, the heat of formation and the standard entropy of formation for each substance at this temperature. In the final column is tabulated the maximum fortuitous error (due to inaccuracies in the values of heats of combustion and entropies) as given by Parks.[35] Although these uncertainties may appear quite large, Parks has stated

---

[32] W. Nernst, *Ann. Physik,* 1911, (4) **36**, 395; *Chem. Zentr.*, 1911, **2**, 1718; *Chem. Abs.*, 1912, **6**, 175; *J.C.S.*, 1911, **100** (2), 964. An aneroid calorimeter with liquid air as heat absorbing agent is used to determine specific heats and latent heats of fusion and vaporization down to about 90°K. (—183°C.). See G. E. Gibson, W. M. Latimer and G. S. Parks, *J.A.C.S.*, 1920, **42**, 1533; *Chem. Abs.*, 1920, **14**, 2880; *J.C.S.*, 1920, **118** (2), 585 and G. S. Parks, *J.A.C.S.*, 1925, **47**, 338; *J.C.S.*, 1925, **128** (2), 491; *Chem. Abs*., 1925, **19**, 1085, for a discussion of the methods employed. See also *Bur. Standards Sci. Paper,* **197** (1913) for the procedure in making the determinations and calculating the heat capacities. In order to obtain entropy values for the range O°K. to 90°K. (—273 to —183°C.) the extrapolation formula of K. K. Kelley, G. S. Parks and H. M. Huffman, *J. Phys. Chem.*, 1929, **33**, 1082; *Brit. Chem. Abs.* **A**, 1930, 24; *Chem. Abs.* 1930, **24**, 775, is used. A synopsis of this method has also been given by G. S. Parks and H. M. Huffman. "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, **1932**, 240.

[33] In the case of liquids, Parks and Huffman use the expression:

$$S_{298} = \int_{0}^{90} \frac{C_{p(\text{crystals})}}{T}\,dT + \int_{90}^{T_M} \frac{C_{p(\text{crystals})}}{T}\,dT + \frac{\Delta H_{\text{fusion}}}{T_M} + \int_{T_M}^{298.1} \frac{C_{p(\text{liquid})}}{T}\,dT$$

where T_M is the melting point of the solid phase and ΔH is the heat of fusion. (All values are per mole.) The first of these integrals is evaluated by the method of K. K. Kelley, G. S. Parks and H. M. Huffman, *loc. cit.* The remaining integrals are most readily determined by graphical integration. In the case in which the standard state of the substance under investigation is gaseous, it is necessary to add two more terms involving the heat of vaporization and the specific heat of the vapor in a manner analogous to that given above. See G. S. Parks and H. M. Huffman, *loc. cit.*, for examples illustrating this general method.

[a] E.U. is the abbreviation generally used for "entropy units" (cal. per degree absolute per mole).

These free energy values have been calculated by Parks[36] on the basis of the latest thermal data available, and supersede the respective figures previously given by Parks and Huffman.[37] The heats of combustion used for determining the heats of formation for all of these hydrocarbons except dodecane are the results of Rossini.[38] For the latter hydrocarbon (dodecane), the combustion data used is that of Banse and Parks[39] corrected according to the method of Washburn.[40] In calculating ΔS°_{298} for the formation of the hydrocarbons, Giauque's[41] value of 15.615 E.U. for $\frac{1}{2}H_2$ (obtained from spectroscopic determinations)[42] and that of Jacobs and Parks,[43] 1.36 E.U. for graphitic carbon, have been employed. The entropies of the hydrocarbons are from the following sources: that of methane is based on the results of statistical determinations of Giauque, Blue and Overstreet[44] and Kassel,[45] while that of ethane is the mean of third law estimates given by Parks and Huffman[46] and statistical determinations of Mayer, Brunauer and Mayer[47] and of Smith and Vaughan.[48] In the absence of any available entropy data for propane, Parks has obtained this value as a direct interpolation of the entropies of ethane and *n*-butane. The latter value and also that of dodecane are those of Huffman, Parks and Barmore.[49] For *n*-pentane, the figure is that of Parks and Huffman,[50] and for *n*-heptane and *n*-octane, the results are those of Parks, Huffman and Thomas.[51]

[42] The calculation of thermodynamic data from spectroscopic determinations has been discussed by L. S. Kassel (*Chem. Rev.*, 1936, **18**, 277; *Chem. Abs.*, 1936, **30**, 5112. The entropy values obtained in this manner are the so-called "absolute" entropies and contain terms which are not measured by specific heat methods, e.g., nuclear spin contributions. The term "entropy" as used in this text is the "practical" entropy, i.e., absolute entropy minus the nuclear spin entropy, or in other words, that quantity which would be obtained from specific heat measurements. See J. D. Kemp and K. S. Pitzer (*J. Chem. Phys.*, 1936, **4**, 749; *Chem. Abs.*, 1937, **31**, 28; *Brit. Chem. Abs.* **A**, 1937 (1), 21) for a discussion of this topic

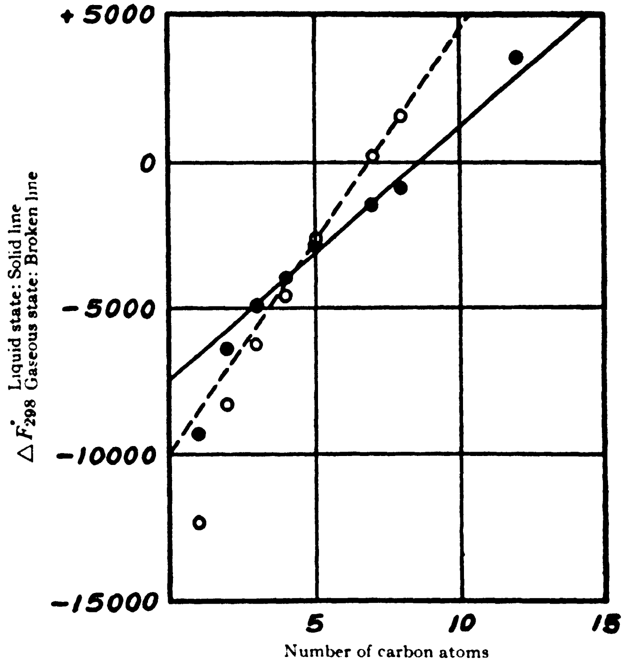
The regularities in the free energies of these hydrocarbons can be readily ascertained from Fig. 315. To facilitate the comparisons in the liquid state, Parks[52] has calculated the hypothetical values for methane (—9,300 cal.), ethane (—6,440 cal.), propane (—4,940 cal.) and *n*-butane (—3,950 cal.). Similarly, for the gaseous state, the theoretical free energies of *n*-pentane (—2,570 cal.), *n*-heptane (190 cal.) and *n*-octane (1,520 cal.) are included. From the graph, it will be seen that the free energies of the paraffins rise appreciably with increasing length of the carbon chain. Above propane the relation between ΔF°_{298} and *n*, the number of carbon atoms, is linear in each case. Thus, for liquid normal paraffins the increase in molal free energy is 860 cal. for each CH_2 increment, whereas for gaseous hydrocarbons it is 1,440 cal.



Courtesy Chemical Reviews, Williams and Wilkins Co.

FIG. 315.—Free Energies of Normal Paraffin Hydrocarbons. (G. S. Parks)

Branched Paraffins. According to Parks and Huffman[53] the molal free energy of the higher paraffins at 298.1°K. (25°C.) appears to increase slightly with increased branchiness of the paraffin, that is, the branched isomers are less stable thermodynamically than the corresponding normal compounds. Parks, Huffman and Thomas[54] have calculated the entropies of 8 isomers of *n*-heptane (2-methylhexane, 3-methylhexane, 3-ethylpentane, 2,2-dimethylpentane, 2,3-dimethylpentane, 2,4-dimethylpentane, 3,3-dimethylpentane and 2,2,3-trimethylbutane) and two of the isomers of *n*-octane (2,2,4-trimethylpentane and hexamethylethane) from low-temperature specific heat measurements in conjunction with the third law. The variations in the individual values of the free energies are rather small and, according to Parks,[55] in some cases not larger than the possible errors in combustion values. The differences between the free energy of the branched isomers and that of the *n*-hydrocarbons have been summarized by Parks and are given in Table 239.

Thomas, *J.A.C.S.*, 1930, **52**, 3241; *Brit. Chem. Abs.* **A**, 1930, 1253; *Chem. Abs.*, 1930, **24**, 4755.

TABLE 239.—*Effects of Branching on Free Energy of Paraffins (in Cal. Per Mole).*

	Number of Branches			
	1	2	3	4
Isoheptanes	0	+1,200	+2,200	
	+1,200	+1,700		
		+600		
Isooctanes			+2,200	+4,500
Average effect of a branch	+750			

Thus, from the table it will be seen that all of these increments, although rather irregular, do show a slight increase in molal free energy with increased branching, leading to a mean value of +750 cal. per branch (either methyl or ethyl group). In one case, however (2-methylpentane), the free energy of the isomer was found to be identical with that of the straight chain hydrocarbon. At first this was attributed to a fortuitous error which might have concealed an effect of only a few hundred calories. On the basis of more recent observations, Parks has suggested that this equality may be real, and that it is even possible that certain lower isoparaffins, such as isobutane, may have a slightly lower molal free energy than the normal compound.

Rossini[56] has calculated the heat of reaction for the transformation of *n*-butane to isobutane in the gaseous phase at 298.1°K. (25°C.) to be:

$$n\text{-}C_4H_{10(g)} = iso\text{-}C_4H_{10(g)};\ \Delta H^{\circ}_{298} = -1{,}630\ (\pm\ 150)\ \text{cal.}$$

Assuming an increase in ΔS°_{298} for this reaction to be —5 E.U. (in accordance with the method of Parks and Huffman[57]), Parks[58] has calculated the free energy change for the isomerization reaction to be $\Delta F = -140\ (\pm 150)$ cal. This figure would indicate that isobutane is slightly more stable thermodynamically than *n*-butane.

Unsaturated Aliphatic Hydrocarbons. The free energy data on the straight and branched unsaturated hydrocarbons are rather scanty. In the case of the olefins, the values on hand, however, do indicate that the effects of increasing length of chain and branching are essentially similar to those of the paraffins. Parks[59] has supplied the data for the first six olefins listed in Table 240. The results for 1,4-pentadiene, *n*-heptane-1 and the two isomers of diisobutylene[60] (that referred to as "low boiling" is thought to be 2,4,4-trimethylpentene-1 and the "high boiling" to be 2,4,4-trimethylpentene-2) have been obtained by Parks, Todd and Shomate[61] and are also included in this table, to which, for comparative purposes, Parks and Huffman's[62] values for acetylene have been added.

The ΔF°_{298} for ethylene, propene, isobutene and the diisobutylenes represent replacements for the corresponding values of Parks and Huffman. For all of the olefins listed in this table, Parks and his collaborators have used ΔH°_{298} data derived from the heats of hydrogenation observed by Kistiakowsky, Romeyn, Ruhoff, Smith and Vaughan[63] and Kistiakowsky, Ruhoff, Smith and Vaughan[64] in conjunction with Rossini's[65] heats of formation for the corresponding paraffins. The entropy of ethylene represents the weighted mean of the results of Smith and Vaughan[66] and Kassel[67] (both obtained from spectroscopic data). In the case of propene, the entropy is that obtained by Huffman, Parks and Barmore.[68] The entropies and free energies of the four butenes are the results given by Todd and Parks[69] and the corresponding values for 1,4-pentadiene, *n*-heptene-1 and the two diisobutylenes, those of Parks, Todd and Shomate.[70] The molal entropies of graphitic carbon and of hydrogen are the values of Jacobs and Parks[71] and Giauque,[72] respectively, as were used in the calculations of Table 238.

In the case of acetylene, the heat of combustion is the mean of that given in the International Critical Tables[73] and that of Mixter.[74] The values of ΔF°_{298} are based on equilibrium measurements of von Wartenberg,[75] Pring[76] and Pring and Fairlie.[77] The entropy values estimated[78] by Parks and Huffman (identified in table by parentheses) give a corresponding free energy of acetylene of 50,640 cal.

From their observations of the isomeric butenes, Todd and Parks[79] have shown that the position of the double bond and geometrical isomerism undoubtedly play important roles in the evaluation of the free energy. According to Parks[80] the introduction of one or more radicals as methyl groups to the carbon atoms adjacent to the double bond exerts a progressive protective action on the double bond. This may be in the form of "spatial screening," tending to render the olefin more like a paraffin hydrocarbon. However, the calculations of Parks, Todd and Shomate[81] on dehydrogenation reactions now furnish a quantitative estimate of this screening effect. According to these authorities, the free energy change for the formation of a normal 1-olefin by dehydrogenation of paraffins in accordance with the general equation:

$$n\text{-paraffin} \longrightarrow n\text{-olefin-1} + H_2$$

is apparently about 21,000 cal., irrespective of the length of carbon chain, except in the case of the ethane-ethylene combination.[82] The addition of other hydrocarbon chains to the carbon atoms adjacent to the double bond lowers the free energy value for the dehydrogenation and in the case of 2,4,4-trimethylpentene-1 (low boiling diisobutylene isomer) is 18,180 cal., according to these authorities. An analogous decrease in ΔF°_{298} when the double bond becomes more centrally located in the molecule was also noted by Todd and Parks in studying the isomeric butenes. For methylbutane to trimethylethylene and tetramethylethane to tetramethylethylene, Parks, Todd and Shomate estimate $\Delta F^\circ_{298} = 17{,}360$ and 17,100 cal., respectively, using heats of hydrogenation obtained by Kistiakowsky, Ruhoff, Smith and Vaughan.[83] The latter figure represents a free energy decrease of approximately 4000 cal. when compared with the normal 1-olefins. Therefore, it will be seen that the substitution of hydrocarbon chains for hydrogen atoms attached to a double bond causes the olefins to become thermodynamically more stable with respect to the corresponding saturated compounds.

The difference between the free energies of ethane and acetylene amounts to almost 60,000 cal. Unfortunately, experimental data on higher members of the acetylene series are entirely lacking, so that comparisons in this respect cannot be made. The exceptionally high value for the free energy (about 25,000 cal. per carbon atom) indicates that at 25°C. acetylene is thermodynamically very unstable with respect to decomposition into carbon and hydrogen.

Cyclic Hydrocarbons. In Table 241 have been summarized the free energies of formation of various cyclic compounds, all of which except cyclopentane (and its derivatives) have been calculated by Parks and Huffman.[84] In this table are included the basic thermal data and the maximum uncertainty in the free energy as estimated by these authorities. The possible errors are, in general, higher than those given in the two preceding free energy tables for paraffins and olefins, and may be attributed mostly to inaccuracies in the heat of combustion values.

---

[78] G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, **1932**, 86. These authorities estimated the absolute entropy of acetylene by subtracting twice the average value (2.7E.U.) observed for the decrease in entropy caused by the insertion of a double bond from the absolute entropy of ethane.

[81] G. S. Parks, S. S. Todd and C. H. Shomate, *J.A.C.S.*, 1936, **58**, 2505.

[82] The free energy values given by Parks (*Chem. Rev.*, 1936, **18**, 325; *Chem. Abs.*, 1936, **30**, 5113) for various dehydrogenations are: ethane to ethylene: 26.000 cal.; propane to propene: 21,040 cal.; and *n*-butane to butene-1: 21.360 cal. Parks, Todd and Shomate (*loc. cit.*) estimate the free energy change for the conversion of *n*-heptane to *n*-heptene-1 to be 20.620 cal. and for *n*-pentane to 1,4-pentadiene: 2 x 21,400 cal.

TABLE 241.—*Molal Free Energies of Formation of Some Cyclic Hydrocarbons.*

	State	S°_{298} E.U.	ΔH°_{298} Cal.	ΔS°_{298} E.U.	ΔF°_{298} Cal.	Maximum Uncertainty (±) in ΔF°_{298} Cal.
Cyclopentane	1	49.4	−29,450	−113.5	4,400	2000
Methylcyclopentane	1	59.2	−37,800	−136.0	2,700	2000
1,2-Dimethylcyclopentane	1	64.5	−47,650	−163.2	1,000	2000
Cyclohexene	1	51.8	−15,290	−112.2	18,200	2000
Cyclohexane	1	49.2	−36,700	−146.0	6,800	1000
Methylcyclohexane	1	59.3	−46,550	−168.4	3,600	2000
Benzene	1	41.9	11,630	−59.4	29,400	1000
Toluene	1	52.4	2,180	−81.6	26,500	1000
Ethylbenzene	1	61.2	−5,070	−105.4	26,300	2000
o-Xylene	1	59.3	−4,670	−107.3	27,300	2000
m-Xylene	1	60.3	−4,670	−106.3	27,000	2000
p-Xylene	1	60.5	−8,470	−106.1	23,200	2000
Naphthalene	s	39.9	15,960	−98.0	45,200	1000

All of the values given above (except those of cyclopentane and its derivatives) represent revisions by Parks and Huffman of earlier work. The combustion data from which the heats of formation were calculated for the naphthenes, cyclohexene and naphthalene are taken from the International Critical Tables,[85] and for the benzenoid hydrocarbons, from the results of Swietoslawski and Bobinska.[86] The entropies of all of the hydrocarbons were calculated from low temperature heat capacity measurements, using the third law of thermodynamics. For cyclohexene and methylcyclohexane these entropy values were determined by Parks and Huffman.[87] The entropies of cyclohexane and toluene are those obtained by Parks, Huffman and Thomas[88] and Kelley,[89] respectively, and those of the other benzenoid hydrocarbons are from the work of Huffman, Parks and Daniels.[90] Giauque's[91] entropy for hydrogen (S°_{298} = 15.615 E.U. for $\frac{1}{2}H_2$) and that of Lewis, Gibson and Latimer[92] (1.3 E.U.) for graphitic carbon were employed in calculating the change in entropy for these hydrocarbons. All of the data on cyclopentane have been calculated by Jacobs and Parks[93] and that for methyl and dimethyl cyclopentane by Huffman, Parks and Barmore.[94]

In the case of all of the cyclic hydrocarbons given above, it will be seen that the thermodynamic stability is increased by the introduction of side chains (i.e., the molal free energy becomes less). With benzene and its various methyl derivatives, however, the effect is very pronounced, as is shown in Fig. 316, in which the molal free energies in the liquid state for benzene, toluene, the three xylenes, pseudocumene (1,2,4-trimethylbenzene), the three tetramethylbenzenes, pentamethylbenzene, and hexamethylbenzene are plotted against the number of side chains. The molal free energies of these compounds reach a minimum with the tetramethylbenzenes, and then increase, so that, according to Parks,[95] the effect of adding one methyl group is apparently the same as the addition of six.

The respective ΔF°_{298} values of cyclopentane and cyclohexane are not directly comparable as regards ring stability, because these compounds contain different numbers of carbon atoms. According to Parks and Huffman[96] on the basis of the free energy per carbon atom, the cyclopentane ring is slightly more stable than the cyclohexane ring. However, considering the rather large uncertainty in the free energy values, especially in the case of the former compound, this view may be subject to change.

Other Organic Compounds. That definite free energy relations exist among the organic compounds of carbon, hydrogen and oxygen is evidenced in Fig. 317 of Parks and Huffman.[97] In this graph, the molal free energies of some aliphatic compounds containing one or two atoms of oxygen are plotted against the number of carbon atoms. In each case, the free energy values of the substances in their standard states (25°C.) have been used, so that most apply to the liquid state. The introduction of oxygen into a compound results in a very marked lowering of the molal free energy, that is, oxygenated substances are much more stable thermodynamically than hydrocarbons of the same number of carbon atoms. In any homologous series, according to Parks and Huffman, the trend in the free energies is probably similar to that of the normal paraffins, especially after the first few members of the series have been passed.

Estimation of Molal Entropy and Free Energy of Compounds from the Structure of the Molecule

Parks and Huffman[98] have pointed out the fairly regular changes in the molal entropy and free energy caused by variations in the structure of organic compounds. These generalizations are often helpful in predicting both entropy and free energy values of substances in the absence of actual experimental data. In the case of the hydrocarbons, the entropy and molecular structure are apparently related by a simple linear function. In this respect, the normal paraffins and cyclic hydrocarbons may be regarded as the basic structures. With regard to these thermodynamic properties, branched hydrocarbons are considered to be derivatives of

---

[96] G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, 1932. See pp. 95-97 for a discussion of ring stabilities from the standpoint of thermodynamics.

[97] G. S. Parks and H. M. Huffman, *loc. cit.* Space does not permit a review of all the numerous prolific investigations of these authorities and their collaborators on the free energies and entropies of organic compounds. The generalities observed by Parks and Huffman allow an approximation of free energy values for a large number of substances in the absence of experimental data. For details, reference should be made to the above mentioned text.

[98] G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, 1932, Chapter 12. G. S. Parks, *Ind. Eng. Chem.*, 1933, 25, 887; *Brit. Chem. Abs.* A, 1933, 1014; *Chem. Abs.*, 1933, 27, 4473. These deductions are based principally upon the data compiled by Parks and his collaborators in the series of articles listed in the section on Free Energy of Formation.

FIG. 317.—Free Energy Relations Among Aliphatic Compounds Containing Oxygen. (G. S. Parks and H. M. Huffman)

the former type, in which one or more of the hydrogen atoms is replaced by methyl, ethyl or other aliphatic chains. Similarly, oxygen, nitrogen and halogen derivatives can be looked upon as substituted hydrocarbons. Using this method for olefins (viewed as dehydrogenated paraffins), the fluctuation in the predicted entropy values is greater than in the case of most other compounds. Still, especially with monolefins, the errors introduced are not of a very serious nature.

Theoretically, the comparisons between the various compounds should be made in the gaseous state, according to Parks,[99] in order to eliminate the effects of intermolecular attraction. However, the most practical basis is the liquid state, since most of the substances ordinarily studied are liquids at 25°C.[100]

Normal Paraffins. Parks, Huffman and Thomas[101] noted that for the normal paraffin hydrocarbons, the entropy could be expressed by the linear equation:

$$(1)\quad S_{298} = 25.0 + 7.7n$$

where n is the number of carbon atoms in the molecule. From this relation, 25.0 E.U.[102] may be regarded as the basic molal entropy for all of the normal paraffins in the liquid state. In the hypothetical case of liquid methane at 25°C. and 1 atmosphere pressure, the above equation gives

$$S_{298} = 25.0 + 7.7 = 32.7 \text{ E.U.}$$

and for heptane,

$$S_{298} = 25.0 + (7.7 \times 7) = 78.9 \text{ E.U.}$$

Huffman, Parks and Barmore[103] have continued these investigations and found that the differences between predicted and experimental values for molal entropies of various straight chain hydrocarbons were a maximum of about 1 per cent, although ordinarily the deviation was even much less. Fig. 318 shows the graphical representation of this function, plotted between the experimentally determined entropies and the number of carbon atoms in the straight chain.

In a similar manner, Parks and Huffman[104] have calculated that the entropy of normal paraffins in the gaseous state at 25°C. may be expressed as:

$$(2)\quad S_{298} = 34.0 + 10.0n$$

This equation, however, only applies to the first four members of the series which are normally gases at 25°C. and 1 atmosphere. They also suggest

$$(3)\quad S_{298} = 18.0 + 5.8n$$

for the estimation of the entropy of the normal crystalline paraffins.

Branched Paraffins. The substitution of a methyl group as a side chain

---

[99] G. S. Parks, *loc. cit.*

[100] In a few cases where the compound is normally crystalline in its standard state, the procedure of H. M. Huffman, G. S. Parks and A. C. Daniels (*J.A.C.S.*, 1930, 52, 1547; *Chem. Abs.*, 1930, 24, 4755; *Brit. Chem. Abs.* A, 1930, 677) may be employed. The formula for the calculation of the change in entropy of fusion at 25°C. (ΔS_{298}) is:

$$\Delta S_{298} = \frac{\Delta H_{\text{fusion}}}{T_M} - \Delta C_p \ln \frac{T_M}{298.1}$$

where ΔH_{fusion} is the molal heat of fusion in calories and T_M is the melting point, in degrees absolute. These investigators suggest the value 0.05 times the molecular weight for ΔC_p, the difference between the molal heat capacities of the liquid and crystals. This entropy change is added to S_{298} of the liquid to give the corresponding S_{298} for the substances in the solid state.

[101] G. S. Parks, H. M. Huffman and S. B. Thomas, *J.A.C.S.*, 1930, 52, 1032; *Brit. Chem. Abs.* A, 1930, 677; *Chem. Abs.*, 1930, 24, 1839.

[102] E.U. is the abbreviation used for entropy units (calories per degree absolute per mole).

[103] H. M. Huffman, G. S. Parks and M. Barmore, *J.A.C.S.*, 1931, 53, 3876; *Chem. Abs.*, 1931, 25, 5889; *Brit. Chem. Abs.* A, 1931, 1363.

[104] G. S. Parks and H. M. Huffman, *loc. cit.*

for a methylene group in a paraffin molecule is accompanied by a decrease of about 4.5 E.U. per branch in the liquid state, according to Parks, Huffman and Thomas.[105] Thus, the preceding formula may be modified to give:

$$(4)\ S_{298} = 25.0 + 7.7n - 4.5r$$

where n is the total number of carbon atoms in the molecule and r is the number of methyl or aliphatic side chains. These investigators report predicted results in good agreement with observed values for the entropy of the eight isomers of *n*-heptane, 2-methylbutane and 2,2,4-trimethylpentane. Fig. 319 shows the experimentally determined molal entropies of seven of the isomeric heptanes plotted against r, the number of branches in the molecule.

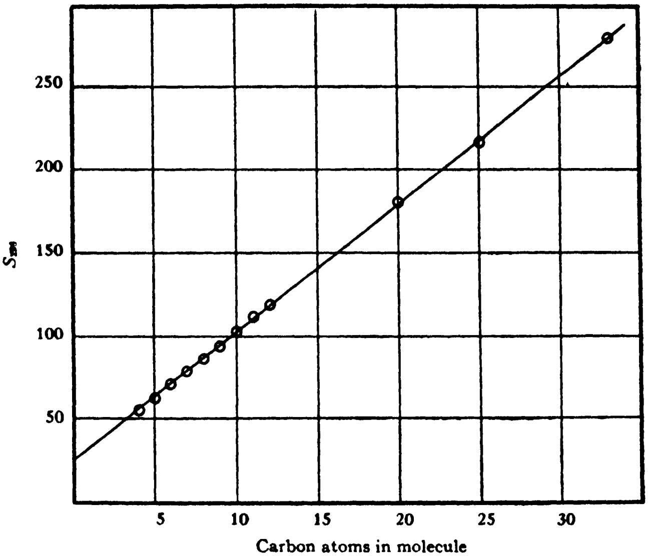

FIG. 318.—Molal Entropies of Normal Paraffin Hydrocarbons, (H. M. Huffman, G. S. Parks and M. Barmore)

Courtesy Journal of American Chemical Society

Aromatic Substituted Hydrocarbons. Huffman, Parks and Daniels[106] revised the above formula to apply to molecules involving phenyl groups, and suggested:

$$(5)\ S_{298} = 25.0 + 7.7n - 4.5r + 19.5p$$

where n is the number of carbon atoms not including the benzene ring, p is the number of phenyl groups in the compound and r is the number of hydrocarbon groups (aliphatic or aromatic, in this case) in excess of two attached to any carbon atoms in the aliphatic chain.[107] These investigators report good agreement between observed and calculated entropies for ethyl benzene, the xylenes, *ter*-butylbenzene, hexamethylbenzene (liquid), diphenylmethane (liquid), triphenylmethane (liquid) and bibenzyl (liquid).[108] That the relation between the molal entropies of the liquid benzenoid hydrocarbons and n, the number of carbon atoms outside the benzene nucleus, is a straight line will be seen from Fig. 320. In this figure, the S_{298} values of benzene, toluene, the three xylenes, pseudocumene (1,3,4-trimethylbenzene), n-butylbenzene, the three tetramethylbenzenes, pentamethylbenzene and hexamethylbenzene have been plotted against the number of carbon atoms outside the benzene ring. According to Parks[109] the somewhat low values for the first and last hydrocarbons may be attributed to the marked symmetry of the molecules involved.

---

[105] G. S. Parks, H. M. Huffman and S. B. Thomas, *J.A.C.S.*, 1930, **52**, 1032; *Brit. Chem. Abs.* **A**, 1930, 677; *Chem. Abs.*, 1930, **24**, 1839.

[106] H. M. Huffman, G. S. Parks and A. C. Daniels, *J.A.C.S.*, 1930, **52**, 1547; *Brit. Chem. Abs.* **A**, 1930, 677; *Chem. Abs.*, 1930, **24**, 2664.

[107] As examples, for *ter*-butylbenzene, n is 4, r is 2 and p is 1; for triphenylmethane, n is 1, r is 1 and p is 3; and for toluene, n is 1, p is 1 and r is 0.

[108] In the case of biphenyl, the observed and calculated values differ by 4 E.U. (about 7 per cent). This may be attributed to too low a value for the heat of fusion, according to H. M. Huffman, G. S. Parks and A. C. Daniels (*loc. cit.*). With benzene (observed S_{298} = 41.9 E.U.) the discrepancy is 2.6 E.U. or about 6 per cent, due probably to its symmetry and unique character, as these authorities state.

Cycloparaffin Substituted Hydrocarbons. By means of a further addition to the last equation, Parks and Huffman have been able to apply it to liquid compounds involving cyclic hydrocarbons, such as cyclopentane and cyclohexane derivatives:

$$(6)\ S_{298} = 25.0 + 7.7n - 4.5r + 19.5p + 26.5p'$$

where n, p and r are the same quantities as above and p' is the number of saturated cyclopentane or cyclohexane rings. Parks calls attention to the fact that the experimentally measured entropy of cyclohexane (49.2 E.U.) is low in comparison with that of methylcyclohexane (59.3 E.U.), on account of the symmetry of the former hydrocarbon.[110]

Olefins. The differences observed in the entropies of various saturated compounds and the corresponding unsaturated ones led Parks and Huffman[111] to propose the additional term, $-2.7e$, to the general entropy equation for liquid hydrocarbons (where e designates the number of double bonds in the molecule). Although this was the average decrease per olefin bond obtained in six cases (pertaining mostly to crystalline unsaturated acids and various cyclic compounds), these investigators stated that, at best, it was only a rough estimation, and lacked the precision of the other terms in the general equation. They further point out that the effect was probably dependent to some extent upon the position of the double bond within the molecule and also upon the influence of neighboring groups. Subsequently, Todd and Parks[112] showed this to be the case in their study of isomeric butenes. However, the latter investigators further noted that the configuration of the molecule must also be considered. Table 242 gives the molal entropies of *cis*- and *trans*-2-butene and isobutene, as determined by Todd and Parks.

---

[109] G. S. Parks, *Ind. Eng. Chem.*, 1933, **25**, 877; *Brit. Chem. Abs.* **A**, 1933, 1014; *Chem. Abs.*, 1933, **27**, 4473.

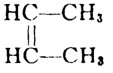
[110] These values were obtained by G. S. Parks, H. M. Huffman and S. B. Thomas, *J.A.C.S.*, 1930, **52**, 1032; *Chem. Abs.*, 1930, **24**, 1839; *Brit. Chem. Abs.* **A**, 1930, 677; and G. S. Parks and H. M. Huffman, *J.A.C.S.*, 1930, **52**, 4381; *Chem. Abs.*, 1931, **25**, 82; *Brit. Chem. Abs.* **A**, 1931, 42.

[111] G. S. Parks and H. M. Huffman, *J.A.C.S.*, 1930, **52**, 4381; *Chem. Abs.*, 1931, **25**, 82; *Brit. Chem. Abs.* **A**, 1931, 42.

TABLE 242.—*Molal Entropies of Three Isomeric Butenes.*

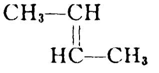
	cis-2-Butene	*trans*-2-Butene	Isobutene
Crystals (0 to 90°K.)	11.70	10.23	10.81
Crystals (above 90°K.)	6.55	11.18	6.17
Fusion	13.06	14.07	10.68
Liquid	19.57	13.61	18.72
Vaporization	20.63	20.41	20.33
Gas (to 298.1°K.)	1.50	1.70	2.29
Absolute Entropy, S°_{298}	73.0	71.2	69.0

Thus, the absolute entropy of the *cis* compound is 1.8 E.U. greater than that of



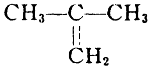
$$\begin{array}{c}HC{-}CH_3\\ \|\\ HC{-}CH_3\end{array}$$

cis-2-butene



$$\begin{array}{c}CH_3{-}CH\\ \|\\ HC{-}CH_3\end{array}$$

trans-2-butene



$$\begin{array}{c}CH_3{-}C{-}CH_3\\ \|\\ CH_2\end{array}$$

isobutene

its stereoisomer, the *trans* modification, and 4.0 E.U. higher than that of isobutene.[113]

The researches of Parks, Todd and Shomate[114] on the heat capacities of some higher olefins (namely *n*-heptene-1, 1,4-pentadiene, and two isomers of diisobutylene) also indicate that the molal entropy is largely dependent upon the symmetry of the molecule and the position of the double bond.[115] The average decrease per olefin bond in these determinations was found to be about 1.4 E.U. per mole. According to these authorities, although this figure cannot be considered very significant, it is probably preferable to the decrease of 2.7 E.U. suggested previously by Parks and Huffman.

Extension to Other Compounds. By means of the above equations, the molal entropy of the various hydrocarbons may be calculated. Parks and Huffman,[116] however, have carried this matter further. On the basis that oxygen, nitrogen and halogen compounds can be considered as derivatives of the various hydrocarbons and by comparisons with experimental data obtained in numerous investigations, these authorities formulated several general rules concerning the relation of entropy and structure. Their deductions, though purely empirical, permit the ready estimation of the S_{298} values for an enormous number of organic compounds, together with the approximate changes in ΔF°_{298} which may be expected due to these structures. Table 243 lists these results of Parks and Huffman.

---

[113] In these experiments, tests were also made on 1-butene which, however, failed to crystallize even at 81.3°K. (−191.8°C.). Todd and Parks estimated the absolute entropy of this isomer to be 72.5 ± 1.3 E.U. per mole.

[b] = Primary OH, −34,000; secondary OH, −37,000

* G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, 1932.

As an example in the use of these data, the entropy of 2,2,3-trimethylbutane may be considered. Using equation for liquid branched paraffins, $n = 7$ and $r = 3$. Therefore

$$S_{298} = 25.0 + (7.7 \times 7) - (4.5 \times 3) = 65.4 \text{ E.U.}$$

It will be noted that this procedure is equivalent to obtaining the entropy of liquid butane by means of equation (1) and adding the effect of the substitution of three methyl groups for hydrogen atoms, taken from Table 243. For instance:

$$S_{298} = 25.0 + (7.7\times4) = 55.8 \text{ E.U.}$$

for liquid butane. The substitutional effect is

$$(3\times3.2) = 9.6 \text{ E.U.}$$

Adding the two gives 65.4 E.U. This predicted value of S_{298} is within 1 per cent of that obtained experimentally (64.8 E.U.) for 2,2,3-trimethylbutane by Huffman, Parks and Thomas.[117] In a similar manner, S_{298} for solid palmitic acid (which Parks and Huffman regard as the derivative of *n*-pentadecane in which one hydrogen atom on the terminal carbon atom has been replaced by a carboxyl group) may be predicted. Thus, for solid *n*-pentadecane ($C_{15}H_{32}$) from equation (3),

$$S_{298} = 18.0 + (5.8\times15) = 105.0 \text{ E.U.}$$

Adding to this value 5.8 E.U. which is the effect for the carboxyl substitution, the resulting entropy value for solid palmitic acid is 110.8 E.U.[118]

VARIATION OF FREE ENERGY WITH TEMPERATURE

Although for convenience in comparisons free energy values are ordinarily tabulated at 298.1°K. (25°C.), a knowledge of the variation of free energy with temperature is important in the case of studies looking to various practical applications, since most reactions are carried out at temperatures other than room temperatures.

From the Gibbs-Helmholtz equation,[119] the change in free energy with respect to temperature at constant pressure may be expressed as:

$$(7)\ \Delta F^{\circ}_{T} = \Delta H_0 - \Delta aT\ln T - \tfrac{1}{2}\Delta bT^2 - \tfrac{1}{6}\Delta cT^3 + IT$$

where ΔF°_{T} is the free energy at the absolute temperature T, ΔH_0 is the basic heat of formation, Δa, Δb and Δc are the constants in the empirical equation for the increase in heat capacity at constant pressure:

$$\Delta C_p = \Delta a + \Delta bT + \Delta cT^2$$

and I is the integration constant.[120] When all of the constants can be evaluated, equation (7) may be used to give the free energy at any temperature. However, as Francis[121] has stated, equations of this nature are very awkward to employ. In general, the curves do not deviate considerably from a straight line, especially in the temperature range of 400-1000°K. (127-727°C.), and therefore Francis recommends the use of a linear function, such as:

$$(8)\ \Delta F = h + kT$$

---

[117] H. M. Huffman, G. S. Parks and S. B. Thomas, *J.A.C.S.*, 1930, **52**, 3241; *Chem. Abs.*, 1930, **24**, 4755; *Brit. Chem. Abs.* **A**, 1930, 1253.

[118] G. S. Parks, K. K. Kelley and H. M. Huffman (*J.A.C.S.*, 1929, **51**, 1969; *Brit. Chem. Abs.* **A**, 1929, 990; *Chem. Abs.*, 1929, **23**, 4877) experimentally determined S_{298} for solid palmitic acid to be 113.7. These values differ by 2.5 per cent.

[119] A rigorous thermodynamic proof of this equation is beyond the scope of this volume. Reference should be made to G. N. Lewis and M. Randall, "Thermodynamics," McGraw-Hill Book Co., Inc., New York and London, **1923**; and H. S. Taylor, "A Treatise on Physical Chemistry," D. Van Nostrand Co., Inc., New York (second edition), **1930**.

[120] The heat content at any temperature T is given by:

$$\Delta H_T = \Delta H_0 + \Delta aT + \tfrac{1}{2}\Delta bT^2 + \tfrac{1}{3}\Delta cT^3$$

From a knowledge of the value of the heat of reaction and the necessary specific heat data, ΔH_0 can be evaluated. By substituting ΔF°_{298} and $T = 298$ in equation (7), I can be determined. For examples of the application of this equation to numerical data, see A. W. Francis, *Ind. Eng. Chem.*, 1928, **20**, 277; *Chem. Abs.*, 1928, **22**, 1131; *Brit. Chem. Abs.* **A**, 1928, 478; and G. S. Parks and H. M. Huffman, *loc. cit.*

[121] A. W. Francis, *Ind. Eng. Chem.*, 1928, **20**, 277, 283; *Chem. Abs.*, 1928, **22**, 1131, 1716; *Brit. Chem. Abs.* **A**, 1928, 478, 479.

where h and k are empirical constants. Equation (8), although only an approximation, is sufficiently accurate for most purposes.[122]

As a test for the similarity of these two equations, Parks and Huffman[123] have calculated the variation in the free energy of formation of ethane following the reaction:

$$(9)\ 2C_{(graph.)} + 3H_{2(g)} = C_2H_{6(g)};\ \Delta F^\circ_{298} = -10{,}700 \text{ cal.}$$

According to equation (7), ΔF°_T for this reaction may be expressed as:

$$(7a)\ \Delta F^\circ_T = -19{,}190 + 15.77T \ln T - 0.0046T^2 - 59.6\,T$$

while from equation

$$(8a)\ \Delta F^\circ_T = -26{,}700 + 51.0T$$

The values for the free energy of ethane at different temperatures, as calculated by these investigators from equations (7a) and (8a) are listed in Table 244.

TABLE 244.—*Free Energy of Ethane at Various Temperatures.*[a]

°K.	400	500	600	700	800	900
°C.	127	227	327	427	527	627
ΔF°_T by 7a	−6,140	−1,360	+3,650	+8,830	+14,150	+19,560
ΔF°_T by 8a	−6,300	−1,200	+3,900	+9,000	+14,100	+19,200
Difference	−160	+160	+250	+170	−50	−360

[a] G. S. Parks and H. M. Huffman. "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, 1932.

From the differences, it will be seen that over this range of temperature (127-627°C.) the results obtained by using the approximate linear relation vary from those of equation (7) by about 1 to 2 per cent, which are well within the limits of experimental error.

Table 245 giving the values of h and k in equation (8) for the variation of free energy of formation of various substances with the temperature has been summarized from data given by Parks and Huffman.[124] The resulting equations are applicable over a temperature range of about 400 to 1000°K. (127 to 727°C.) for substances in the gaseous state. Since these values are based on experimental data which are subject to revision due to inaccuracies in heats of combustion and formation, the probable error in the value of ΔF°_{298} as listed by these investigators is also included.[125]

By combinations of approximate free energy-temperature equations for various compounds, Parks and Huffman have estimated three general formulas for variation of free energy with both temperature and length of the carbon chain. These are:[126]

---

[122] This is especially true when the uncertainty of the free energy values of some of the compounds involved is considered.

[123] G. S. Parks and H. M. Huffman, *loc. cit.*

[124] G. S. Parks and H. M. Huffman, *loc. cit.*

[125] G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, 1932. The probable errors have been estimated by Parks and Huffman and represent the maximum uncertainty in the values given by them in their "Table of Free Energies," p. 231. A. W. Francis has compiled a somewhat similar table to show the variation of free energy and temperature. Unfortunately the ΔF and ΔH values available at that time (1928) were in error to such an extent that they have been superseded by more recent determinations. However, reference should be made to the two articles of Francis mentioned previously for a concise treatment and explanation of the practical application of the principles involved in the above calculations.

[126] For comparative purposes, the equations derived by A. W. Francis (*loc. cit.*) are:

Paraffins: $\Delta F^\circ = -13{,}300 - 7850n + 2.2T + 25.55nT$
Olefins: $\Delta F^\circ = 31{,}060 - 9400n - 39.5T + 25.5nT$
Naphthenes: $\Delta F^\circ = 12{,}900 - 8500n - 19.3T + 25.5nT$
Acetylenes: $\Delta F^\circ = 68{,}400 - 7000n - 61.9T + 25.5nT$
Alcohols: $\Delta F^\circ = -43{,}540 - 7010n + 24.2nT$

where n is the number of carbon atoms and T is the absolute temperature.

for normal paraffins in the gaseous state:

$$(10)\ \Delta F^{\circ}_{\mathrm{T}} = -14{,}700 - 6000n + 1.0T - 25.0nT$$

for normal 1-olefins (hexene-1, octene-1 and so forth):

$$(11)\ \Delta F^{\circ}_{\mathrm{T}} = 5700 - 6500(n - 2) + 21.1T - 24.0(n - 2)T$$

and for normal primary alcohols:

$$(12)\ \Delta F^{\circ}_{\mathrm{T}} = -57{,}000 - 6000(n - 2) + 59.8T + 25.0(n - 2)T$$

where n is the number of carbon atoms and T is the absolute temperature. Fig. 321 is a comparison of the variation of molal free energies of four six-carbon atom hydrocarbons, benzene, hexene-1, n-hexane and cyclohexane in the gaseous state. Although at 400°K. (127°C.) n-hexane is the most stable (indicated by the lower value of ΔF°) and benzene is the least stable, at 1300°K. (1027°C.) this condition is entirely reversed. Analogously, at the lower temperature cyclohexane is slightly more stable than 1-hexene, but above 900°K. (627°C.) the opposite is true.

TABLE 245.—*Constants for Evaluating Free Energy at Various Temperatures Using the General Equation:*

$$\Delta F^{\circ}_{\mathrm{T}} = h + kT$$

	h	k	Maximum Probable Error (±) in Fundamental Value of ΔF°_{298} Cal./Mole
Methane	−19,450	23.0	500
Acetylene	−54,900	−13.6	500
Ethylene	5,700	21.1	2,000
Ethane	−26,700	51.0	1,000
n-Hexene-1	−20,300	117.1	2,000
Cyclohexane	−33,600	136.4	1,000

APPLICATIONS OF FREE ENERGY TO PROBLEMS OF THE PETROLEUM INDUSTRY

The possibilities of the application of free energy data to problems of the petroleum industry are by no means as limited as those which will be discussed in this chapter.[127] However, the examples here cited are of a rather general nature, and may be considered as more or less representative applications.[128]

For convenience, most thermodynamic calculations are based on reactions taking place in the gaseous state. One reason for this has been pointed out by Francis,[129] namely, that general equations can be set up to cover these types of transformations. On the other hand, liquid phase reactions cannot be represented by general equations. However, in the latter case, from a knowledge of the vapor pressure, fugacity[130] or activity[131] of the substance, specific equations to cover each reaction may be readily formulated.

---

[127] Consult A. W. Francis and R. V. Kleinschmidt (*Oil and Gas J.*, 1929, 28 (29), 118; *Amer. Pet. Inst. Bull.*, 1930, III, 93; *J. Inst. Pet. Tech.*, 1930, 16, 3A; *Chem. Abs.*, 1930, 24, 2369) for a discussion of the applications of thermodynamics and its limitations.

[128] It should be noted that in some cases the free energy values that have been used are not the most recent calculations. Refinements such as these will, of course, lessen the amount of uncertainty.

[129] A. W. Francis, *Ind. Eng. Chem.*, 1928, 20, 277; *Chem. Abs.*, 1928, 22, 1131; *Brit. Chem. Abs.* A, 1928, 478.

In some instances certain reactions which normally would be accompanied by a slight increase in free energy can be forced to proceed by the application of pressure, especially if the transformation is accompanied by a decrease in volume. However, Francis[132] has stated that even the use of high pressures will not ordinarily overcome an unfavorable free-energy change of more than about +5000 cal. Still another point emphasized by Francis is that a reaction which is found to be thermodynamically impossible (one in which the free energy change has a value of +10,000 cal. or higher, in a positive sense) cannot be induced to proceed by means of a catalyst.[133]

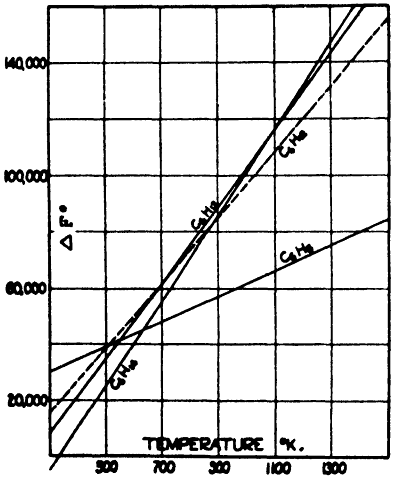

FIG. 321.
Variation of Molal Free Energies of Gaseous *n*-Hexane, 1-Hexene, Cyclohexane and Benzene as Function of Absolute Temperature. (G. S. Parks)

Courtesy Industrial and Engineering Chemistry

At this time it might also be well to restate some of the limitations of thermodynamics. Free energy calculations are based primarily on the concept of equilibrium. In actual practice, especially in cracking, true equilibrium is never attained, but according to Francis, only a condition nearer to this state is reached, and this implies a lower value of free energy. Furthermore, since the important variable, time, does not enter into thermodynamic considerations, no inkling as to the necessary duration for equilibrium to be established is possible. Many reactions appear to occur by concatenation, that is, by chain mechanisms, or by stepwise manners. In these cases, reaction rates, which likewise are beyond the scope of this science, play an important and perhaps even a predominating role.[134] Finally, it should also be remembered that the standard free energy values apply to substances in their standard state (one atmosphere pressure and 25°C.). The actual free energies of substances involved in reactions may differ appreciably from those under the assumed ideal conditions, and therefore should be corrected to the corresponding circumstances.[135]

---

[130] Fugacity may be regarded as a corrected or effective vapor-pressure, i.e., the actual vapor pressure of a substance as differentiated from the theoretical vapor pressure that would be expected from calculations involving the use of the ideal gas laws. See G. N. Lewis and M. Randall ("Thermodynamics," McGraw-Hill Book Co., Inc., New York and London, 1923) for a discussion of this concept.

[131] Activity is a corrected or effective concentration, made necessary due to deviations of actual substances from ideality, usually applied to substances in the liquid state. See G. N. Lewis and M. Randall, *loc. cit.*

[132] A. W. Francis, *loc. cit.*

[133] In this respect, the possible error in the value of the free energy figures as given in the preceding table should be borne in mind. Thus, if the free energy of a reaction has been calculated to be 10,000 cal., but due to uncertainties in the free energies of formation that are involved (which errors may either be accumulative or compensating) there may be a factor of ± 5000 cal. to be considered. The above statement is of necessity subject to revision, as the free energy change for the reaction probably lies between +15,000 and +5000 cal., and if the latter value is the correct one, the reaction may proceed with catalysts.

Bearing the above discussion in mind, examples of the use of free energy calculations in cracking, hydrogenation and dehydrogenation, polymerization, the preparation of olefins, isomerization, the hydration of olefins, the Fischer synthesis and a few other general applications will be reviewed.[135a]

Cracking. A general discussion of the thermodynamics of cracking in reference to the work of Schultze[136] has already been given. Parks and Huffman[137] have also studied the application of this science to typical cracking reactions. Table 246 has been compiled from their calculations, and represents four types of rupture for *n*-tetradecane in the gaseous phase. The approximate equation expressing the free energy change with temperature is given in the first column, and in the second and third are listed the corresponding free energies at 600°K. (620°F.) and 1000°K. (1340°F.), respectively.

TABLE 246.—*Free Energy Changes for the Vapor Phase Cracking of n-Tetradecane.*

	ΔF°_T	ΔF°_{600} (620°F.)	ΔF°_{1000} (1340°F.)
(13) $C_{14}H_{30} = C_{12}H_{26} + CH_4 + C$..........	$-7,450 - 27T$	$-23,600$	$-34,400$
(14) $C_{14}H_{30} = C_8H_{18} + C_6H_{12}$ (hexene).....	$15,700 - 33T$	$-4,000$	$-17,200$
(15) $C_{14}H_{30} = C_8H_{18} + C_6H_{12}$ (cyclohexane).	$2,400 - 13.6T$	$-5,800$	$-11,200$
(16) $C_{14}H_{30} = C_8H_{18} + C_6H_6 + 3H_2$........	$53,900 - 108T$	$-11,100$	$-54,400$

Reaction (13) involves cracking to a lower paraffin with the simultaneous formation of methane and the deposition of carbon. In equation (14) the decomposition is to *n*-octane and hexene. In equations (15) and (16) the products are *n*-octane and cyclohexane and *n*-octane, benzene and hydrogen, respectively.

Concerning these reactions, all of which are thermodynamically feasible as indicated by the large negative values of ΔF° even at 600°K. (620°F.), it is impossible to predict just which one will predominate at any particular temperature. This is a typical case in which a knowledge of the various rates of reaction is required to establish the point. Thus, by use of specific catalysts, any one of these reactions might become the predominating one. Again, it is necessary to remember the equilibrium conditions assumed, and since these conditions cannot be attained, the corresponding free energy values should be somewhat lower. Parks and Huffman, however, suggest that in the absence of any data on the reaction rates, the magnitude of the free energy change may be taken as a crude criterion for the relative importance. In accordance with this assumption, at 600°K. (327°C.)

---

[134] This matter will be discussed in more detail later in this chapter.

[135] In view of the magnitude of the uncertainty of most free energy values for organic compounds, this procedure is ordinarily not required. However, for the exact application of thermodynamics, corrections of this nature should be made. See G. N. Lewis and M. Randall, *loc. cit.*; and H. S. Taylor, "A Treatise on Physical Chemistry," D. Van Nostrand Co., Inc., New York, **1930**.

[135a] Evaluation of chemical reactions from the standpoint of thermodynamics has also been given consideration in previous portions of this text. Note especially Chapters 3, 26, 36 and 52.

[136] G. R. Schultze, *Angew. Chem.*, 1936, **49**, 268; *Chem. Abs.*, 1936, **30**, 6176; *Brit. Chem. Abs.* **B**, 1936, 535. See Chapter 3. This work of Schultze was based primarily on the general formulas of G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, **1932**.

[137] G. S. Parks and H. M. Huffman, *loc. cit.* Consult H. L. Hays (*Oil and Gas J.*, 1936, **34** (49), 39; *Chem. Abs.*, 1936, **30**, 5401) for a thermodynamic analysis of the reactions involved in cracking lower hydrocarbons, such as propane. Also M. W. Travers, *J. Inst. Fuel*, 1935, **8**, 157; *Brit. Chem. Chem. Abs.* **B**, 1935, 391; *Chem. Abs.*, 1935, **29**, 7935.

equation (13) might be expected to predominate and at 1000°K. (727°C.), equation (16).

Francis[138] has stated that liquid-phase cracking reactions are accompanied by lower free energy values, indicating slightly less thermodynamic favorability. The values for the corresponding liquid-phase reactions may be calculated, provided the partial pressures of the compounds involved are known.

Dehydrogenation. The change in ΔF accompanying the dehydrogenation of the lower paraffins has been investigated by Frey and Huppke.[139] These investigators obtained the necessary experimental data from equilibrium constant measurements at various temperatures, using an air-dried chromic oxide gel catalyst. Table 247 gives their equations for the change in ΔF for the dehydrogenation reactions and the value of ΔF at 673°K. (400°C.).

TABLE 247.—*Free Energies of Dehydrogenation of Lower Paraffins.*

	ΔF_T	ΔF_{673} (400°C.)
$C_2H_6 = C_2H_4 + H_2$	$27,798 - 9.21T \log T + 2.17T$	11,730
$C_3H_8 = C_3H_6 + H_2$	$25,920 - 9.21T \log T - 0.21T$	8,250
$n\text{-}C_4H_{10} = C_2H_5CH{=}CH_2 + H_2$	$25,790 - 9.21T \log T - 0.21T$	8,120
$n\text{-}C_4H_{10} = cis\text{-}CH_3CH{=}CHCH_3 + H_2$	$25,580 - 9.21T \log T - 0.21T$	7,910
$n\text{-}C_4H_{10} = trans\text{-}CH_3CH{=}CHCH_3 + H_2$	$25,090 - 9.21T \log T - 0.21T$	7,420
$iso\text{-}C_4H_{10} = (CH_3)_2C{=}CH_2 + H_2$	$23,900 - 9.21T \log T - 0.21T$	6,230

According to Frey and Huppke, the error in ΔF over the range of 300 to 600°C. is in no case more than several hundred calories. From their values of ΔF_{673} (400°C.) it will be seen that the dehydrogenation of the lower members of the paraffin series proceeds to only a very limited extent, even under equilibrium conditions and using a selective catalyst. At higher temperatures, especially in the case of the large molecular weight hydrocarbons, Frey and Huppke conclude that this type of decomposition may be expected.

Hydrogenation. The theoretical thermodynamic considerations of the hydrogenation of unsaturated hydrocarbons have been discussed by Sweeney and Voorhies.[140] For the hydrogenation[141] of benzene to cyclohexane, for instance, the standard free energy change may be represented by:

$$(17)\quad C_6H_{6(g)} + 3H_{2(g)} = C_6H_{12(g)};\ \Delta F_T^{\circ} = -51,500 + 94.7T$$

where T is the absolute temperature and each substance is assumed to be at 1 atmosphere pressure. At other partial pressures[142] (designated by p) of the three reactants, the above equation takes the form:

$$(18)\quad \Delta F = -51,500 + 94.7T + RT \ln \frac{p_{C_6H_{12}}}{p_{C_6H_6} \cdot p^3_{H_2}}$$

When equilibrium is attained in the system ($\Delta F = 0$), rearrangement of equation (18) gives:

$$(19)\quad \log \frac{p_{C_6H_{12}}}{p_{C_6H_6}} = \frac{11,250}{T} - 20.7 + 3 \log p_{H_2}$$

[140] W. J. Sweeney and A. Voorhies, Jr., *Ind. Eng. Chem.*, 1934, **26**, 195; *Chem. Abs.*, 1934, **28**, 2168; *Brit. Chem. Abs.* **B**, 1934, 438; *J. Inst. Pet. Tech.*, 1934, **20**, 165A.

[141] For a general discussion of hydrogenation of oils, see E. J. Gohr and R. P. Russell, *J. Inst. Pet. Tech.*, 1932, **18**, 595, 358A; *Chem. Abs.*, 1932, **26**, 4941; *Brit. Chem. Abs.* **B**, 1932, 919.

[142] This procedure is based on ideal conditions, i.e., assumption that the ideal gas laws hold. For high pressures, the fugacity, or effective pressure should be substituted. See G. N. Lewis and M. Randall, "Thermodynamics," McGraw-Hill Book Co., New York and London, **1923**.

Sweeney and Voorhies have substituted values of $T = 672°K.$ (750°F.) and 812°K. (1000°F.) in equation (19) and plotted the functions, as shown in Fig. 322. Thus, it is evident that the equilibrium ratio of cyclohexane to benzene increases sharply in proportion to the rise in hydrogen pressure. At 750°F. this quotient is 0.0001, corresponding to 1 atmosphere of hydrogen. At the same temperature and 150 atmospheres of hydrogen, the ratio of the partial pressure of cyclohexane to benzene is approximately 300. Thus, according to these investigators, it should be theoretically possible to obtain any degree of hydrogenation at a certain temperature by the appropriate choice of hydrogen pressure.

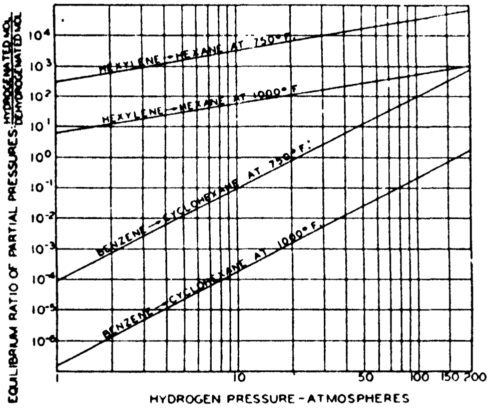

FIG. 322.
Effect of Temperature and Pressure in Simple Hydrogenation of Benzene and Hexene. (W. J. Sweeney and A. Voorhies)

Courtesy Industrial and Engineering Chemistry

The analogous case of the hydrogenation of hexene to hexane has also been discussed by Sweeney and Voorhies. When each of the substances is at 1 atmosphere pressure, the equation

$$C_6H_{12(g)} + H_{2(g)} = C_6H_{14(g)};\ \Delta F_T^\circ = -30{,}400 + 33.9T$$

gives the standard change in free energy. Likewise at other partial pressures of the three substances and at equilibrium, this transformation may be represented by:

$$\log \frac{p_{C_6H_{14}}}{p_{C_6H_{12}}} = \frac{6{,}650}{T} - 7.41 + \log p_{H_2}$$

Assuming the same temperatures as in the previous case, from Fig. 322 it will be seen that the equilibrium ratio of the partial pressures of hexane to hexene is greater than that of cyclohexane to benzene (in the preceding instance) indicating that the saturation of the olefin to give the corresponding paraffin should proceed quite readily even at 1 atmosphere pressure of hydrogen. The effect of hydrogen pressure is less pronounced in the case of the hexene-hexane equilibrium than in that of the benzene-cyclohexane reaction, as is shown by the slopes of the respective isotherms.

Polymerization. Parks[143] has stated that the well known tendency of the lower olefins to undergo polymerization may be readily explained by means of free energy calculations. One example, that of the dimerization of isobutene, has already been discussed.[144] Another illustration, that of the polymerization of

[143] G. S. Parks, *Ind. Eng. Chem.*, 1933, **25**, 887; *Chem. Abs.*, 1933, **27**, 4473; *Brit. Chem. Abs.* **A**, 1933, 1014.

[144] See Chapter 26.

hexene-1 to dodecene, will now be considered. Parks has employed ΔF°_{298} values of 14,900 and 21,000 cal., respectively, for these two substances[145] and represented the change in ΔF_{298} for this reaction as:

$$2C_6H_{12(l)} = C_{12}H_{24(l)};\ \Delta F^{\circ}_{298} = 21{,}000 - 2(14{,}900) = -8{,}800 \text{ cal.}$$

From this large negative free energy, Parks concluded that the liquid phase polymerization of an olefin, such as hexene-1, should be virtually complete,[146] even at 25°C.

Production of Isooctane. Vast interest has been shown in the synthetic production of isooctane (2,2,4-trimethylpentane), due to the antiknock properties of this hydrocarbon as a motor fuel.[147] Parks and Todd[148] have investigated the thermodynamic considerations involved in the preparation of this hydrocarbon from isobutene and suggest two mechanisms, both of which will now be discussed.

The first method for producing isooctane involves the polymerization of isobutene to diisobutylene and subsequent hydrogenation to isooctane. For the first step, the change in free energy is given as:

$$(20)\quad 2C_4H_{8(g)} = C_8H_{16(l)};\ \Delta F^{\circ}_{298} = -6{,}930 \text{ cal.}$$

and for the second step:

$$(21)\quad C_8H_{16(l)} + H_{2(g)} = C_8H_{18(l)};\ \Delta F^{\circ}_{298} = -20{,}280 \text{ cal.}$$

Thus, even at 25°C. the rather large negative values of ΔF°_{298} indicate that thermodynamically the reactions may be expected to proceed quite spontaneously and completely from left to right. Parks and Todd allege that these two reactions may be carried out readily even at room temperatures with the proper choice of catalysts. Assuming approximate linear relations for the change in free energy with temperature (that is, taking $\Delta C_p = 0$) equation (20) results in

$$(20a)\quad \Delta F^{\circ}_T = -26{,}770 + 66.6T$$

and equation (21) in

$$(21a)\quad \Delta F^{\circ}_T = -28{,}470 + 27.5T$$

The latter equations show that the free energy will be negative below 402°K. (129°C.) and 1035°K. (762°C.), respectively, both of which are above the boiling points of diisobutylene (101°C.) and isooctane (99°C. for 2,2,4-trimethylpentane).

Considering now the production of both diisobutylene and isooctane in the gaseous phase, the equations become:

$$(20b)\quad \Delta F^{\circ}_T = -17{,}920 + 42.2T$$

from which $\Delta F^{\circ} = 0$ at 425°K. (152°C.) and

$$(21b)\quad \Delta F^{\circ}_T = -28{,}570 + 26.7T$$

from which $\Delta F^{\circ} = 0$ at 1035°K. (762°C.). By the use of moderate pressures (up to 10 atmospheres) of isobutene, Parks and Todd believe that the production of gaseous diisobutylene should be perfectly feasible up to about 200°C.

---

[145] Estimations of the free energies of these substances may be made from the general equations for the free energy of formation of olefins [equation (11)] by substituting $T = 298$ and $n = 6$ and 12, respectively. An alternative method would be to use the general equation for the free energy of formation of paraffins [equation (10)] and add on 20,000 cal., for the effect of the double bond, as given in Table 243.

[146] See Chapter 26, this text.

[147] See, for example, Chapters 3, 26 and 44 of this text.

[148] G. S. Parks and S. S. Todd, *Ind. Eng. Chem.*, 1936, **28**, 418; *J. Inst. Pet. Tech.*, 1936, **22**, 253A; *Chem. Abs.*, 1936, **30**, 3401; *Brit. Chem. Abs.* **A**, 1936, 701.

The second method of producing isooctane outlined by Parks and Todd[149] involves the union of isobutene and isobutane, according to the equation:

$$(22)\quad C_4H_{10(g)} + C_4H_{8(g)} = C_8H_{18(l)};\ \Delta F^\circ_{298} = -8{,}250 \text{ cal.}$$

The approximate general equation for the change in free energy as a function of the temperature is:

$$(22a)\quad \Delta F^\circ_T = -27{,}100 + 63.2T$$

from which ΔF° is negative up to 429°K. (156°C.). However, the corresponding equation for the production of gaseous isooctane is

$$(22b)\quad \Delta F^\circ_T = -18{,}350 + 39.1T$$

which gives negative values for the free energy up to 469°K. (196°C.). Parks and Todd state that the latter reaction is not feasible with moderate pressures of isobutane and isobutene at temperatures in excess of 225°C. At this temperature $\Delta F^\circ_{498} = 1{,}130$ cal. and K_p is 0.3, corresponding to about a 6.7 mole per cent concentration of isooctane in equilibrium with 7 atmospheres of isobutane and 7 atmospheres of isobutene.

Parks and Todd assert that the relatively low temperatures required by the above thermodynamic considerations, together with the low reaction velocity and chemical inertness associated with the paraffin hydrocarbons, tend to make reaction (22) appear rather dubious. However, these authorities point out the fact that this type of reaction[150] (especially one involving a tertiary carbon atom, as isobutane) may be made to proceed by means of special catalysts, and cite as an example the work of Ipatieff and Grosse.[151] The latter investigators studied reaction (22) using a catalyst of powdered nickel, boron trifluoride and water, at 25°C., and obtained a 32 per cent yield of octanes. Likewise, experimentally the upper temperature limit of this reaction was found to be about 200°C., which is in essential agreement with the predictions of thermodynamics.

Isomerization. The conversion of cyclohexane into methylcyclopentane may be cited as an example of isomerization. Parks[152] has calculated the free energy change for this transformation in the liquid phase at 25°C. to be:

$$C_6H_{12(l)} = C_5H_9CH_{3(l)};\ \Delta F^\circ_{298} = -4{,}100 \text{ cal.}$$

However, due to the low reactivity of these two hydrocarbons at ordinary temperatures, equilibrium could not probably be reached within reasonable time limits. From Table 241 the change in heat content for this reaction may be calculated as

$$(-37{,}800) - (-36{,}700) = -1{,}100 \text{ cal.}$$

and assuming the change in molal heat capacities of the two hydrocarbons are equal, the approximate equation

$$\Delta F^\circ_T = -1{,}100 - 10T$$

is obtained. Although this equation was based on the liquid phase reaction, according to Parks, it can be applied as a rough approximation to the gaseous phase conversion, since the boiling points and consequently the free energies and heats of vaporization of cyclohexane and methylcyclopentane do not differ very greatly. Thus, at 773°K. (500°C.) the free energy for the gaseous reaction is

—8,800 cal. In this respect, it is of interest to note that numerous investigators have identified methylcyclopentane among the products obtained in the catalytic reactions of cyclohexane. For instance, Aschan[153] reported that by heating the latter hydrocarbon with fuming hydriodic acid at 300°C., it was converted into methylcyclopentane. Anhydrous aluminum chloride was found not to effect the transformation, as was subsequently verified by Nenitzescu and Cantuniari.[154] These latter investigators, however, observed that by adding traces of water to the aluminum chloride catalyst, yields of as high as 20 per cent of methylcyclopentane could be obtained by heating cyclohexane for 3 hours at about 80°C. Ipatieff and Komarewsky[155] also reported a pronounced conversion to methylcyclopentane with a mixed catalyst of gaseous hydrogen chloride and aluminum chloride.

Hydration of Ethylene. The free energy change involved in the production of ethyl alcohol from ethylene[156] has been the subject of much discussion. Considerable discrepancy exists between the calculations based upon the existing thermodynamic data and those derived from experimental observations, as pointed out by Gilliland, Gunness and Bowles.[157]

These investigators studied the reaction

$$C_2H_{4(g)} + H_2O_{(g)} = C_2H_5OH_{(g)}$$

over a range of temperatures of 175 to 310°C. and pressures of 82.6 to 264.2 atmospheres, using dilute sulphuric acid as a catalyst. From equilibrium data obtained in these experiments, the free energy for the reaction was calculated by means of the equation:

$$\Delta F_T^\circ = -RT \ln \frac{(yf)_{C_2H_5OH}}{(yf)_{C_2H_4}\,(yf)_{H_2O}}$$

where y is the mole fraction of the substance in the vapor phase and f is the fugacity in atmospheres of the pure gas at the temperature in question and at a pressure equal to the total pressure, R is the gas constant and T is the absolute temperature.[158] It was also found that the change in free energy with temperature for this reaction could be expressed by the approximate relation:

$$\Delta F_T^\circ = -7{,}780 + 26.2T$$

This equation correlates well with the experimental work of Sanders and Dodge,[159] Bowles,[160] and Stanley, Youell and Dymock[161] but does not agree with the values of Francis and Kleinschmidt[162] and Parks and Huffman,[163] both of which were based on thermal computations. However, Gilliland, Gunness and Bowles point out that the ΔF°_{298} value of Francis and Kleinschmidt is in good agreement with that obtained by extrapolation of the experimental values, while that of Parks and Huffman is not.[164]

[158] According to these authorities, the use of pressures in place of fugacities produces relatively small errors in the free energy values (for instance, at 200 atmospheres, the difference amounts to about 10 per cent). This may be explained by the fact that ethylene acts like an ideal gas under these conditions, and that the deviations of ethanol and water from ideality tend to cancel, since they occur in the free energy equation as a ratio.

[163] G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, **1932**.

Gilliland, Gunness and Bowles[165] suggest the equation:

$$\Delta F^\circ = -8{,}300 + 26.9T$$

to correlate all of the experimental data mentioned above on the vapor phase hydration of ethylene. This expression is said to be accurate to within ± 500 cal. It is noteworthy that by using dilute sulphuric acid catalysts, liquid-phase concentrations of ethanol as high as 18 per cent were obtained by these investigators. However, they found that the temperature range for the production of ethanol is limited to 220 to 250°C., as below the first temperature ether is formed, and above the latter temperature, polymerization of ethylene interferes.

Production of Higher Alcohols by Hydration. It is interesting to note the thermodynamic possibilities of the direct hydration of some of the higher olefins to alcohols.[166] Eberz and Lucas[167] have studied the equilibrium between isobutene, water and *ter*-butyl alcohol using a dilute nitric acid catalyst. From calculations of the quilibrium constant for the reaction:

$$C_4H_{8(g)} + H_2O_{(l)} = C_4H_9OH_{(l)}$$

at 25°C. and 35°C., they obtained $\Delta F^\circ_{298} = -1{,}330\ (\pm 20)$ cal. and $\Delta F^\circ_{308} = -946$ cal., respectively. These values show that the production of *ter*-butanol is thermodynamically possible even at ordinary temperatures.

Parks[168] has estimated the free energy change in the hydration of hexene-1 to *sec*-hexyl alcohol for the liquid phase process at 25°C. to be approximately 600 cal.[169] Provided chemical inertness is not too great an obstacle, Parks believes that it may be possible to carry out this hydration even at room temperature. However, for the production of *n*-hexyl alcohol from hexane and water, the accompanying free energy change is about 22,000 cal., so that this reaction is unfeasible.

The Fischer Synthesis (Synthol). The synthesis of higher alcohols from carbon monoxide and hydrogen[170] under high pressure may be taken as an illustration of the use of free energy in substantiating a mechanism proposed for a given reaction. For instance, Frolich and Cryder[171] have stated that it is generally conceded that the high molecular weight products are not formed directly in one step, but are the resultants of a series of several reactions. Methanol is undoubtedly an important intermediate in all of these operations.

---

[164] In this respect, it should be noted that the ΔF°_{298} values for ethylene (+12,300 cal.) and for ethyl alcohol (−42,200 cal.) are listed by Parks and Huffman as both being uncertain to the extent of ± 2,000 cal. More recent determinations have shown (see Table 240) that the value for ethylene should have been + 15,820 (± 3000) cal., so that the error in this compound alone was almost equal to that assumed for the total reaction

[165] E. R. Gilliland, R. C. Gunness and V. O. Bowles, *loc. cit.*

[169] This result is based on free energies of formation given by G. S. Parks and H. M. Huffman (*loc.* cit.) and may entail a fortuitous error of ±3000 cal.

[170] For a discussion of the thermodynamics of the Fischer-Tropsch Synthin (Kogasin) process, by which hydrocarbons are produced by the catalytic reduction of carbon monoxide, see Chapter 52.

[171] P. K. Frolich and D. S. Cryder, *Ind. Eng. Chem.*, 1930, **22**, 1051; *Brit. Chem. Abs.* **A**, 1930, 1553; *Chem. Abs.*, 1930, **24**, 5717.

Considering first the production of methanol, Parks and Huffman[172] point out that this substance may be formed by the trimolecular reaction:

$$(23)\quad CO + 2H_2 = CH_3OH_{(g)};\ \Delta F^\circ = -22{,}800 + 55.1T$$

or by the two bimolecular reactions advanced by Frolich and Cryder:

$$(24)\quad CO + H_2 = HCHO_{(g)};\ \Delta F^\circ = -1300 + 26.7T$$

and

$$(25)\quad HCHO_{(g)} + H_2 = CH_3OH_{(g)};\ \Delta F^\circ = -21{,}500 + 28.4T$$

involving the formation of formaldehyde and subsequent reduction to methanol. In Fig. 323 Parks and Huffman have plotted the change in free energy with temperature for these reactions (indicated by (23), (24) and (25), respectively). For reaction (23) the free energy change at 600°K. (327°C.) will be +10,000 cal. for the standard state reaction (assuming methanol to be produced at one atmosphere pressure). But by increasing the partial pressure of the hydrogen and carbon monoxide each to 100 atmospheres, Parks and Huffman calculated that the value of ΔF_{600} will be in the magnitude of −6500 cal. Therefore, under the latter conditions, this trimolecular reaction appears very feasible. Similarly, high pressures

FIG. 323.—Change in Free Energy with Temperature for Reactions Involved in Synthesis of Alcohols from Carbon Monoxide and Hydrogen. (G. S. Parks and H. M. Huffman)

---

[172] G. S. Parks and H. M. Huffman, "The Free Energies of Some Organic Compounds," The Chemical Catalog Co., Inc., New York, 1932, 224. All of the free energy-temperature relations in the present discussion have been calculated by Parks and Huffman. Their equations for methyl alcohol, formaldehyde, ethyl alcohol and acetic acid may be obtained from Table 245. The other approximate equations for the evaluation of change in free energy of formation with temperature that they used are:

$$CO_{(g)}:\ \Delta F^\circ_T = -26{,}500 - 20.7T$$

$$H_2O_{(g)}:\ \Delta F^\circ_T = -58{,}350 + 12.5T$$

and

$$CH_3CHO_{(g)}:\ \Delta F^\circ_T = -43{,}400 + 37.1T$$

are required for the Frolich and Cryder mechanism. Parks and Huffman state that under the above conditions of temperature and pressure equation (24) only becomes feasible if the partial pressure of formaldehyde is kept at about 0.01 atmospheres. However, the partial pressure of the latter substance will depend upon the relative rates[173] of reactions (24) and (25).

According to Fischer[174] the production of higher alcohols may be represented by a series of equations involving primarily the combination of carbon monoxide and methanol to form acetic acid, and the subsequent reduction of this compound to acetaldehyde and finally to ethanol. Using Parks and Huffman's equations for the free energy change with temperature gives:

$$(26)\ CH_3OH_{(g)} + CO = CH_3COOH_{(g)};\ \Delta F^\circ = -29{,}500 + 33.4T$$
$$(27)\ CH_3COOH_{(g)} + H_2 = H_2O + CH_3CHO_{(g)};\ \Delta F^\circ = 3550 + 3.1T$$
$$(28)\ CH_3CHO_{(g)} + H_2 = C_2H_5OH_{(g)};\ \Delta F^\circ = -13{,}600 + 22.1T$$

However, on the basis of experimental observations, Frolich and Cryder disagreed with the mechanism proposed by Fischer and advanced the possibility of a reaction involving the dehydration of two molecules of methanol to form one of ethyl alcohol, as for instance:

$$(29)\ 2CH_3OH_{(g)} = H_2O_{(g)} + C_2H_5OH_{(g)};\ \Delta F^\circ = -16{,}750 + 3.5T$$

Referring again to Fig. 323 it will be seen that the mechanism of Frolich and Cryder is consistent with thermodynamic considerations over the entire temperature range, having a fairly constant value of —13,000 cal. This indicates a large driving force for the dehydration reaction. The equations of Fischer, however, involve reaction (27) for the reduction of acetic acid to acetaldehyde, for which the free energy change is approximately 5000 cal. Offhand, it might therefore be concluded that the Fischer mechanism is incorrect, since one of the standard state reactions involved is thermodynamically unfeasible. However, Parks and Huffman have calculated that at 600°K. (327°C.), with partial pressures of acetic acid vapor, hydrogen, water vapor and acetaldehyde of 1.0, 200, 1.0 and 0.1 atmospheres, respectively, $\Delta F_{600} = -3700$ cal. Thus, although from the theoretical equations this reaction appeared to be very doubtful, under actual operating conditions it may very likely proceed. Parks and Huffman conclude, however, that the mechanism of Frolich and Cryder is undoubtedly the more feasible for explaining this synthesis.

From the above considerations, it will be seen that corrections are often necessary to allow for actual operating conditions. Thus reaction (23) had a standard state free energy (ΔF°_{600}) of +10,000 cal. at 600°K. (327°C.), but under actual operating conditions with high pressures of carbon monoxide and hydrogen, the actual free energy is much different (in the case cited, $\Delta F_{600} = -6500$ cal.). However, when the standard state free energy for a transformation is in the magnitude of +20,000 to 30,000 cal. or more, Parks and Huffman state that the reaction is thermodynamically untenable.[175]

ENGINEERING THERMODYNAMICS

The first portion of this chapter has been devoted to a discussion of thermodynamics as relating to chemical transformations. However, another phase of this science, that dealing with physical changes in a system, is important in engineering calculations. Therefore, the remainder of this chapter will be devoted to a summary of the data available for this branch of thermodynamics directly applicable to petroleum problems and to methods of empirically estimating such data in the absence of experimental values.

---

[173] Thus, if the speed of reaction (25) is sufficient to allow no accumulation of formaldehyde, the above partial pressure may result.

[174] F. Fischer, "The Conversion of Coal into Oils," translated by R. Lessing, D. Van Nostrand Co., New York, 1925.

[175] From the above discussion it should be noted that a certain compound may often be produced by more than one reaction, theoretically, at least, in a complex system. Although it may be thermodynamically impossible to account for the presence of this substance by one reaction, another equation or series of equations may be postulated which can explain the apparent discrepancy. This is one of the difficulties at present inherent in petroleum thermodynamics.

The thermodynamic variables most generally employed in engineering calculations, together with their symbols and units, are listed in Table 248.

TABLE 248.—*Thermodynamic Variables for Engineering Calculations.*

		Units	
	Symbol	British System	Metric System
Pressure	P	lbs. per sq. in.	kg. per sq./cm.
Temperature	T	°R. (Rankine, °R. = °F. + 460)	°K. (Kelvin, °K. = °C. + 273)
Volume	V	cu. ft.	liters
Heat Capacity (constant pressure)	C_p	B.t.u. per lb. per °R. (or °F.)	cal. per gram per °K. (or °C.)
Heat Content	H	B.t.u.	cal.
Entropy	S	B.t.u. per °R. (or °F.)	cal. per °K. (or °C.)

The first three of the above variables, pressure, temperature and volume, are in very common usage. They are related by the equation of state, for instance, in the case of an ideal gas, $PV = NRT$, where N is the number of moles and R is the gas constant. The remaining properties, heat capacity, heat content and entropy, are essential in evaluating energy transformations, and merit some further discussion

The heat capacity (or specific heat) may be regarded as the quantity of heat that is required to raise the temperature of one unit of the material under consideration one degree (using consistent units). The heat content, or total heat or enthalpy, as it is sometimes called, is a very useful quantity, since changes in this property indicate directly the quantity of heat gained or lost by a system of constant mass undergoing a transformation at constant pressure. On the other hand, the entropy indicates how any variation in a system affects the ability of that system to do useful work, since the entropy is a measure of the waste thermal energy.

The mathematical relations between Cp, H and S can be best seen from the fundamental partial differential equations:[176]

$$(28)\ C_p = \left[\frac{\delta H}{\delta T}\right]_p \quad \text{and} \quad (29)\ \frac{C_p}{T} = \left[\frac{\delta S}{\delta T}\right]_p$$

Equation (28) may be expressed in words as: the heat capacity at constant pressure is equal to the rate of change of heat content with respect to temperature at constant pressure. Similarly, equation (29) may be stated as the heat capacity at constant pressure, divided by the absolute temperature is equal to the rate of change of entropy with respect to temperature at constant pressure. Under isobaric conditions, therefore, the integrated forms of the above expressions become:

$$(28a)\ dH = \int C_p dT \quad \text{and} \quad (29a)\ dS = \int \frac{C_p dT}{T}$$

respectively.

In general, these thermodynamic properties may be tabulated for each hydrocarbon, not unlike the "steam tables" for the case of water. However, as Lacey and Sage[177] have stated, the graphical representation of these quantities is distinctly advantageous and convenient. For instance, in a simple chart plotted between the temperature as ordinate and the entropy as abscissa, lines of constant pressure, constant volume and constant heat content may be drawn, thus including the complete data for one substance on a single chart.[178]

---

[176] Space does not permit a complete discussion of the numerous thermodynamic equations and relations existing between all these variables. Consult G. N. Lewis and M. Randall. "Thermodynamics," McGraw-Hill Book Co., Inc., New York and London, 1923. J. H. Perry, "Chemical Engineers' Handbook," McGraw-Hill Book Co., Inc., New York and London, 1934. The fundamental principles may be found in most elementary volumes on thermodynamics.

Before entering upon a discussion of the charts of this nature and their use it is advisable to review some of the empirical relations that have been developed and may be used in estimating thermodynamic properties both of pure hydrocarbons and mixtures (for instance, petroleum fractions) in the absence of experimental data.

One empirical constant, the Universal Oil Products characterization factor, K (usually referred to as the U.O.P. characterization) has been found to have quite a broad applicability for estimating and correlating various physical and thermal properties of petroleum fractions. In light of this, a brief discussion of this constant is in order.

THE U.O.P. CHARACTERIZATION FACTOR

From data on the physical properties of pure hydrocarbons, Watson and Nelson[179] have observed that the ratio of the cube root of the absolute boiling point to the specific gravity is substantially a constant for the paraffin hydrocarbons boiling between 100 and 700°F. When the boiling point is expressed in degrees Rankine (Fahrenheit, absolute) and the specific gravity at 60°F. referred to water at the same temperature, this ratio varies between 12.5 and 12.8 for paraffin hydrocarbons, whereas for aromatics, the value is 9.8. The definition of the U.O.P. characterization factor arose from the above observations. For narrow-boiling fractions of a crude oil which contains predominantly hydrocarbons of one type, the cube root of the "molal average boiling point" is approximately proportional to the specific gravity of the fraction or:

$$(30)\quad K = \frac{\sqrt[3]{T_B}}{s}$$

where K is the U.O.P. characterization factor, T_B is the molal average boiling point in degrees Rankine (°R = °F. + 460), and s is the specific gravity at 60/60°F.[180] For narrow boiling fractions, the Engler 50 per cent point may be taken as the average boiling point.[181] However, when mixtures of wide boiling range are used, a special method for estimating this quantity must be employed, as will be discussed shortly.

According to Watson and Nelson, the characterization factor denotes what may be termed the "paraffinicity" of the hydrocarbon fraction. Thus, stocks predominantly paraffinic in nature are represented by a factor of 12.5 or thereabout. Fractions that are highly aromatic or naphthenic have a considerably lower characterization, approaching a value of 10 as a minimum. Egloff and Nelson[182] have listed the following values of characterization factors for typical petroleum stocks:

---

[177] W. N. Lacey and B. H. Sage, *Oil and Gas J.*, 1934, **33** (26), 86; *Chem. Abs.*, 1935, **29**, 585; *J. Inst. Pet. Tech.*, 1935, **21**, 122A.

[178] Lines of constant values are given special designations on these charts. For instance, lines of constant temperature are known as isotherms, lines of constant volume are isochores and of constant pressure, isobars.

[179] K. M. Watson and E. F. Nelson, *Ind. Eng. Chem.*, 1933, **25**, 880; *Chem. Abs.*, 1933, **27**, 5522; *Brit. Chem. Abs.* **B**, 1933, 995; *J. Inst. Pet. Tech.*, 1933, **19**, 408A.

[180] The symbol 60/60°F. is often used, and signifies that density of the material in question has been measured at 60°F. and is referred to water also at 60°F.

Recycle stocks	10.0-11.0
Cracked residuums	9.8-11.0

Estimation of Average Boiling Point. Watson and Nelson[183] have pointed out that there are several different methods for establishing a so-called average boiling point of petroleum hydrocarbons. By calculating an integrated average ordinate of the true boiling point curve, an accurate average boiling point may be obtained, either on a volumetric or a weight basis, depending upon the units on which the distillation curve is plotted.[184] An Engler distillation curve gives a fair approximation to the volumetric average boiling point, with a tendency toward higher values than would result by averaging a volumetric true boiling point curve. These investigators prefer to use the "molal average boiling point."

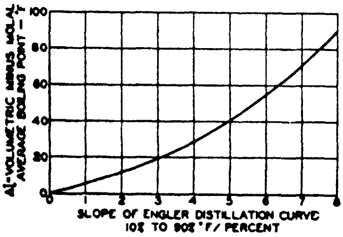

FIG. 324.
Correction Curve for Obtaining Approximate Molal Average Boiling Points. (K. M. Watson and E. F. Nelson)

Courtesy Industrial and Engineering Chemistry

This quantity is less than the volumetric average because of the fact that the ratio of the specific gravity to the molecular weight is higher for the low-boiling members of a hydrocarbon series. Thus, in determining the average boiling point from a volumetric distillation curve, the lower boiling fractions should be given increased weighting in proportion to the variation with boiling point of this ratio of specific gravity to molecular weight, according to Watson and Nelson.

These authorities proposed to obtain an approximation for the molal average boiling point by applying a correction factor to the volumetric average boiling point. This correction factor (see Fig. 324) is expressed as a function of the slope of the 100 cc. Engler distillation curve, and becomes zero as the slope of the curve approaches zero (denoting a pure substance). To obtain the volumetric average boiling point, it is ordinarily sufficient to average the temperatures at which the percentage over plus the distillation loss (in the 100 cc. Engler distillation test) equals 10, 30, 50, 70 and 90 per cent. The slope to be used in Fig. 324 is obtained by dividing the difference between the 90 per cent point and the 10 per cent point by 80. The number of degrees to be subtracted from the volumetric average boiling point is then read from the chart.

When dealing with high-boiling stocks where the temperatures in the distillation exceed 700°F. (which may cause the material to undergo partial cracking), Watson and Nelson prefer to use data from a reduced pressure distillation, correction to atmospheric pressure being made by means of a vapor pressure chart. However, if low-pressure distillation data are not available on these high-temperature stocks, these authorities state that the 50 per cent point probably offers a better approximation to the average boiling point than would that value obtained by averaging the temperatures of the atmospheric distillation curve.

---

[183] K. M. Watson and E. F. Nelson, *loc. cit.*
[184] See Chapter 50, this text.

On the basis of later data, Watson, Nelson and Murphy[185] have suggested a more accurate method for approximating the average molal boiling points. For Engler slopes of 3 or less, Fig. 324 is satisfactory. However, where the Engler slope is 8.0, better correlation results when a correction of approximately 60°F. rather than the 90°F. indicated on Fig. 324 is used. Intermediate corrections are similarly reduced. These investigators also state that for close-cut fractions with slopes of 1.5 or less, this correction factor may be neglected and the 50 per cent temperature taken as the average boiling point.

ESTIMATION OF THE CHARACTERIZATION FACTOR

The U.O.P. characterization factor, *K*, may be calculated by means of equation (30) from a knowledge of the specific gravity and the average boiling point. Watson, Nelson and Murphy have also found that viscosities, aniline points, viscosity indices and hydrogen contents of petroleum fractions could also be used for evaluating this constant. Of these methods, however, that based on the viscosity is the most universal in its application.

Thus, if the kinematic viscosity at 210°F. (in centistokes[186]) and the gravity (in °A.P.I.) of the oil are known, the characterization factor may be obtained by interpolation of the curves given in Fig. 325. Similarly, from the kinematic viscosity at 122°F. or 100°F. and the gravity, K may be read from Figs. 326 and 327, respectively. The lines of constant boiling point plotted in Figs. 325, 326 and 327 are the resultants of a combination of the relationships between the characterization factor from both boiling point and viscosity data. (These lines permit an approximation of the boiling point from only viscosity and gravity data.) Egloff and Nelson[187] have pointed out that the relationship is particularly useful in the case of heavy stocks on which boiling point data can be obtained only under reduced pressure. However, because of the rapid change in viscosity with a slight variation in the gravity of heavy stocks, estimations such as these may be considerably in error, sometimes as high as 50°F. for the heavier residuums.

MOLECULAR WEIGHT OF PETROLEUM FRACTIONS

Watson and Nelson[188] have stated that methods for relating the molecular weight of petroleum fractions to any other single physical property have proved rather unreliable, except for a few limited cases. However, by correlation of two properties, such as specific gravity and boiling point, a relationship can be established which is said to be satisfactory for most purposes. Using the characterization factor and the molal average boiling point, the molecular weight may be obtained with errors less than 5 per cent, according to these investigators, from Fig. 328. Similarly, from the gravity of the oil (in °A.P.I.) and the molal average boiling point, the molecular weight may be estimated from the curves shown in Fig. 329. However, for accurate calculations, Watson and Nelson recommend that an experimental determination of the molecular weight is to be employed whenever possible.

ESTIMATION OF THE CRITICAL TEMPERATURE

Eaton and Porter[189] have developed an empirical equation for evaluating the critical temperature of a substance, based on the 50 per cent A.S.T.M. boiling point[190] and the specific gravity. This relation, which was derived from data on both pure hydrocarbons and various petroleum fractions, may be stated as:

$$t_c = 180 + 1.75a - 0.00088a^2$$

[189] G. L. Eaton and C. A. Porter, *Ind. Eng. Chem.*, 1932, **24**, 819; *Brit. Chem. Abs.* **B**, 1932, 825; *Chem. Abs.*, 1932, **26**, 4450.

[190] See Carleton Ellis, "The Chemistry of Petroleum Derivatives," The Chemical Catalog Co., Inc., New York, **1934**. See also Chapter 50 this text.

where $a = (t_b + 100)s$, t_c = critical temperature (°F.), t_b = 50 per cent point (A.S.T.M. distillation) and s = specific gravity at 60°F. Fig. 330 is a graphical representation of this function, by means of which the critical temperature may be determined directly if the 50 per cent point and the specific gravity are known. According to Eaton and Porter, the average deviation in the values of the observed and calculated critical temperatures is about 8°F., although for pure hydrocarbons of higher molecular weight than propane, the average difference is about 5.5°F.

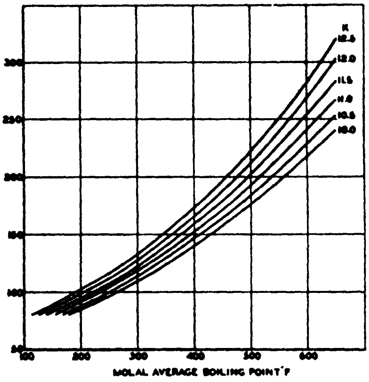

FIG. 328.
Correlation of Characterization Factors and Average Molecular Weights of Petroleum Fractions. (K. M. Watson and E. F. Nelson)

Courtesy Industrial and Engineering Chemistry

Watson and Nelson,[191] however, believe that the use of the molal average boiling point gives a more logical correlation on stocks of wide boiling ranges than does the use of the A.S.T.M. distillation 50 per cent point, as proposed by Eaton and Porter. In Fig. 331 is plotted the relation between the critical temperature (in°F.) and the molal average boiling point for various values of the A.P.I. gravity, as calculated by Watson and Nelson. An illustration of the applicability of this method has been cited by the same workers using the data of Bahlke and Kay[192] for a gasoline and a close-cut naphtha of substantially the same molecular weight and specific gravity. The properties of the two stocks are listed in Table 249.

FIG. 329.
Average Molecular Weights of Petroleum Fractions as Functions of A.P.I. Gravity and Molal Average Boiling Point. (K. M. Watson and E. F. Nelson)

[191] K. M. Watson and E. F. Nelson, *loc. cit.*

[192] W. H. Bahlke and W. B. Kay, *Ind. Eng. Chem.*, 1929, **21**, 942; *Chem. Abs.*, 1930, **24**, 230; *Brit. Chem. Abs.* **B**, 1929, 1004.

TABLE 249.—*Properties of Gasoline and Naphtha of Equal Molecular Weight.*

	Gasoline	Naphtha
Molecular weight (determined)	109	110
Gravity	57.3	57.1
A.S.T.M. distillation curve:		
10%	149	230
30%	230	245
50%	282	258
70%	325	272
90%	371	295
Slope of A.S.T.M. curve	2.8	0.81
Volumetric average b.p.	271	260
Critical temperature (determined)	586	591
Molal average b.p. (from Fig. 324)	254	256

These data show that the gasoline is a lighter stock of lower molecular weight and critical temperature than the naphtha. However, both the 50 per cent point and the volumetric average boiling point are considerably higher than those of the naphtha. When the boiling point is corrected to a molal average basis (by use of Fig. 324) the values of both the average boiling point and the critical temperature fall in the proper order. From Fig. 331 the critical temperatures of these stocks are estimated as 584 and 587°F., respectively.

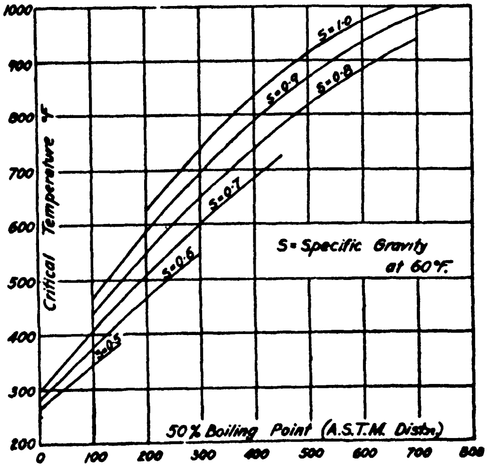

FIG. 330.
Chart for Estimation of Critical Temperatures of Petroleum Fractions from A.S.T.M. 50 Per Cent Boiling Point. (G. L. Eaton and C. A. Porter)

Courtesy Industrial and Engineering Chemistry

The critical temperature may also be estimated in terms of the characterization factor, from the chart prepared by Watson, Nelson and Murphy[193] and given in Fig. 332. This chart may be used to estimate the characterization factor, molecular weight and critical temperature of petroleum fractions from the A.P.I. gravity and the molal average boiling point. Thus, the latter two quantities determine one point on the graph, and by interpolation between the corresponding constant-value lines for characterization factor, molecular weight and critical temperature, the desired property may be approximated.

[193] K. M. Watson, E. F. Nelson and G. B. Murphy, *Ind. Eng. Chem.*, 1935, 27, 1460; *Chem. Abs.*, 1936, 30, 3974.

ESTIMATION OF THE CRITICAL PRESSURE

Determination of the critical pressures of hydrocarbon mixtures is difficult and quite susceptible to large errors unless special precautions are taken. However, Watson and Nelson[194] have proposed a method which offers fair correlation with the available data. This scheme is based on the method of plotting vapor pressure data suggested by Cox[195] for estimating the critical pressure of a pure hydrocarbon whose critical temperature is known. The vapor pressure curves for the pure hydrocarbon when plotted in this manner form straight lines converging at a single point. The critical pressure of a compound whose critical temperature is known may be obtained by drawing a line connecting the normal boiling point of the compound to the point of convergency. The critical pressure is now read from the point of intersection of the vapor pressure curve and the critical temperature abscissa.

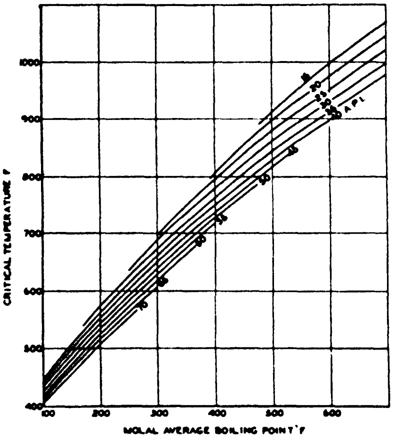

FIG. 331.
Critical Temperatures of Petroleum Fractions from A.P.I. Gravity and Molal Average Boiling Point. (K. M. Watson and E. F. Nelson)

Courtesy Industrial and Engineering Chemistry

Watson and Nelson observed that the average boiling points of mixtures of hydrocarbons usually are approximately straight lines on the Cox chart, and, furthermore, that these lines have the same point of convergency as the pure hydrocarbons. Similarly, the curves representing conditions of initial equilibrium vaporization also are straight lines on the Cox chart, provided the stocks do not contain large quantities of dissolved gases. The investigators point out that the slope of the initial vaporization curve is considerably less than that of the average boiling point curve, so that these two lines intersect at a point beyond the critical temperature of the fraction. As a fair approximation, they found that the latter point of intersection may be assumed to lie at a point beyond the intersection of the average boiling point line and the critical temperature abscissa by a distance equal to 0.2 times the distance between the latter intersection and the atmospheric average boiling point. The temperature of the initial equilibrium vaporization at atmospheric pressure may be taken as the Engler distillation 10 per cent point, in accordance with the views of Bridgeman, Aldrich and White.[196] These assumptions permit an approximation for the initial vaporization line to be established

FIG. 332.—Diagram Correlating Molecular Weights, Critical Temperatures and Characterization Factors of Petroleum Fractions. (K. M. Watson, E. F. Nelson and G. B. Murphy)

on the Cox chart. The critical pressure is then obtained as the pressure corresponding to the intersection of this initial vaporization line with the critical temperature abscissa.

---

[196] O. C. Bridgeman, E. N. Aldrich and H. S. White, *Bull. Am. Pet. Inst.*, 1930, 11 (1), 4; *Chem. Abs.*, 1930, 24, 1966.

An illustration of this method has been given by Watson and Nelson,[197] using the data of Weir and Eaton[198] for a naphtha having the following characteristics:

A.P.I. Gravity	58.2
A.S.T.M. Distillation:	
10%	157
30%	211
50%	259
70%	303
90%	353
Volumetric Average B.P.	256
Molal Average B.P. (Predicted from Fig. 324)	241

From Fig. 332, the critical temperature is estimated to be 571°F. The procedure for graphically estimating the critical pressure of this stock is shown in Fig. 333. The series of slanting lines on this chart are the vapor pressure curves for the various paraffin hydrocarbons (the number at the top of the lines refers to the number of carbon atoms in the molecule). The line *FC* is the critical temperature abscissa of this particular naphtha (571°F.). *AB* is the average boiling point line drawn through the atmospheric average boiling point *A* (241°F.) and the point of convergency of the pure hydrocarbon lines. Point *D* is located by measuring along line *AB* a distance of 0.2 times the length of *AC*. Point *E* is the A.S.T.M. 10 per cent point (157°F.). The critical temperature and pressure are represented by point *F*, corresponding to 571°F. and 530 lbs. per sq. in. (absolute). Watson and Nelson point out that these values are in good agreement with the values predicted by Weir and Eaton from the thermal behavior of this distillate, namely 575°F. and 500 lbs. per sq. in.

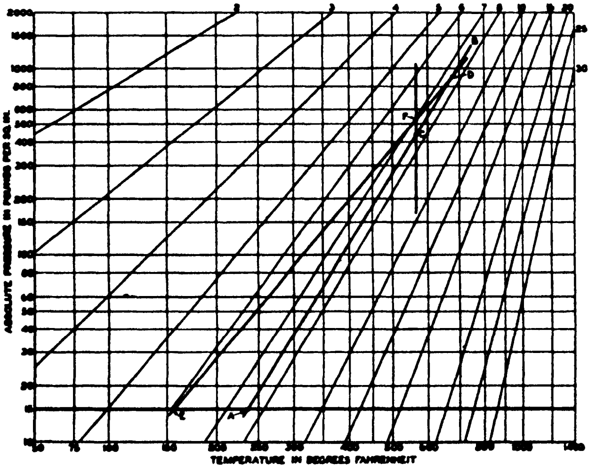

FIG. 333. Chart for Estimating Critical Pressures of Petroleum Fractions. (K. M. Watson and E. F. Nelson)

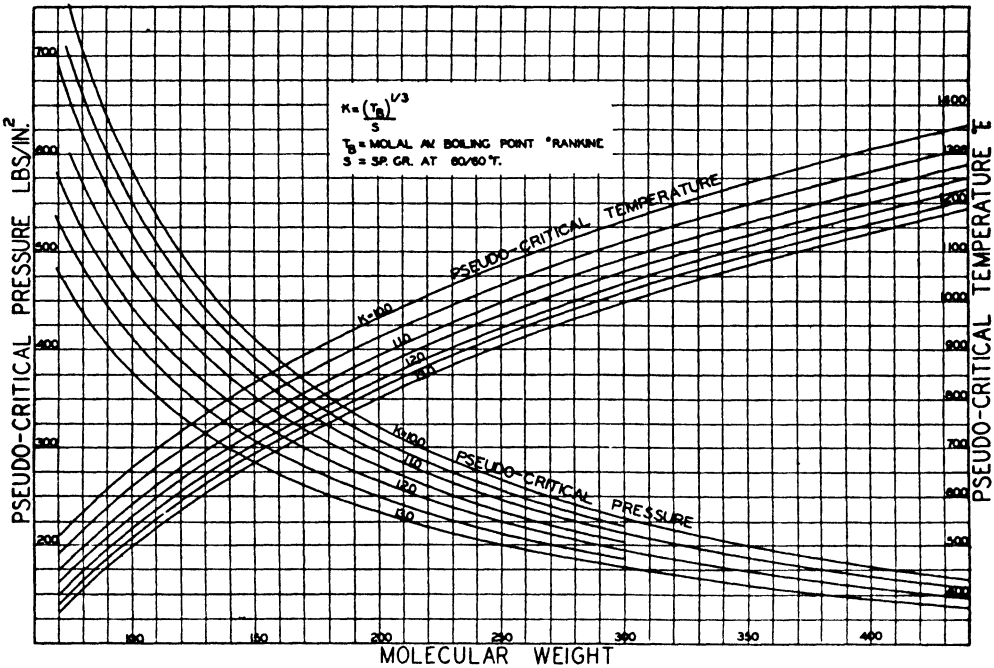
Fig. 334.—Curves Relating Boiling Points and Critical Pressures of Hydrocarbons. (G. Egloff and E. F. Nelson)

chart of Coats and Brown,[200] and is shown in Fig. 334. From this graph, the critical pressure of the hydrocarbons is determined from the molal average boiling point and the critical temperature. The small curve plotted in the upper corner of this figure shows the correction factor by which the critical pressure of a pure compound is multiplied to obtain the critical pressure of a mixture having the same average boiling point, gravity and critical temperature. This correction factor is related to the slope of the Engler distillation curve in the same manner as that of Fig. 324. The latter method is a convenient means of approximation, and is said to be in fair agreement with the available data.



Courtesy Industrial and Engineering Chemistry

FIG. 335.—Pseudocritical Temperatures and Pressures of Hydrocarbon Mixtures. (W. B. Kay)

Kay[201] has correlated the pseudocritical temperatures and pressures[202] of hydrocarbons in terms of the characterization factor and the molecular weight of the fraction. These relations are given in Fig. 335. According to Kay, the critical values of mixtures composed of lower molecular weight hydrocarbons may be estimated with an error of 2 or 3 per cent. However, in the case of higher molecular weight fractions, the error may be somewhat greater.[203]

---

[201] W. B. Kay, *Ind. Eng. Chem.*, 1936, **28**, 1014; *Chem. Abs.*, 1936, **30**, 7828; *Brit. Chem. Abs.* **A**, 1936, 1330.

[202] The "pseudocritical point" of a mixture corresponds to the critical point of a pure hydrocarbon of the same physical characteristics (i.e., molecular weight, boiling point and so forth). According to W. B. Kay (*loc. cit*), the pseudocritical point of a mixture has no real existence and therefore cannot be measured. Only for mixtures of very narrow boiling range is it approximately equal to the true critical point.

Pressure-Volume-Temperature Relations of Hydrocarbons

The introduction of high temperature and high pressure developments in the petroleum field has necessitated a knowledge of the properties of the substances under these conditions. Especially in the gaseous or vapor phase are materials sensitive to changes in temperature and pressure, as Lewis[204] has pointed out. The ideal gas laws are exact only at very low pressure, and it was generally recognized that in some instances deviations of from 10 to 20 per cent were not uncommon, even when dealing with pressures of 100 to 200 lbs. per sq. in. However, these errors were seldom as large as other uncertainties in design problems, and therefore, ordinarily, engineers did not hesitate to take advantage of the simplicity of these relations. But in the case of high pressure operations, it was found that these deviations may reach several hundred per cent and as such would have to be considered in calculations.

Reduced Equation of State. The so-called reduced equation of state offers a possible basis for the generalized treatment of gases and vapors. Designating the pressure, volume and temperature of a substance at the critical point as P_c, V_c and T_c, respectively, the values of these quantities under any other conditions may be expressed as a ratio (commonly known as the reduced property) in terms of the critical constants. Thus, the reduced pressure is $P_r = \frac{P}{P_c}$, where P is the pressure and P_c is the critical pressure for the material under consideration. Similarly, the reduced volume may be expressed as $V_r = \frac{V}{V_c}$, and the reduced temperature as $T_r = \frac{T}{T_c}$.

For one mole of a material, regardless of the deviation of the vapor from the ideal gas laws, the equation of state may be written as $PV = \mu RT$, where R is the gas constant and μ is the correction factor to allow for deviation (necessarily a dimensionless ratio).[205] Substituting for the three variables in the above equation their equivalents in terms of the critical and reduced properties gives:

$$\frac{P_r V_r}{T_r} = \frac{\mu R T_c}{P_c V_c}$$

Lewis states that if, for a given group of substances a single reduced equation of state exists (as designated mathematically by the notation $V_r = f\ (P_r,\ T_r)$ where f represents the same function for the entire group), regardless of how complicated this relationship may be, it must reduce to the above form at sufficiently low pressure values. However, the right-hand side of this equation is a constant for a given compound, and so it follows that this constant must be identical for all substances of the group. Thus, Lewis believes that a common reduced equation of state is impossible except for substances having identical critical ratios of

$$\frac{RT_c}{P_c V_c}.$$

---

[203] Consult L. C. Roess (*J. Inst. Pet. Tech.*, 1936, **22**, 665; *J. Inst. Pet. Tech.*, 1936, **22**, 539A) for a discussion of the development of a flow method for determining the critical temperature and pressure of petroleum fractions up to 1000° F. and 600 lbs. per sq. in., respectively, and the correlation between these properties and other physical properties which are more readily determined.

[204] W. K. Lewis, *Ind. Eng. Chem.*, 1936, **28**, 257; *Chemistry and Industry*, 1936, 123; *Chem. Abs.*, 1936, **30**, 1893; *J. Inst. Pet. Tech.*, 1936, 22, 146A; *Brit. Chem. Abs.* **B**, 1936, 255.

[205] Thus for an ideal gas, since $\mu = 1$, $PV = RT$. A dimensionless ratio is a pure number, i.e., one which requires no qualifying units.

Correlation of P-V-T Data. A survey of the available data on hydrocarbons by Brown, Lewis and Weber[206] showed that a reduced equation of state was applicable to all compounds of this type above propane. According to Lewis,[207] the experimental data for all hydrocarbons indicates a maximum deviation of about 12 per cent in the critical ratio. However, when the low-boiling compounds of small molecular weight are excluded, this variation does not exceed 3 per cent. Therefore, it is permissible to compare the P-V-T characteristics of hydrocarbons containing more than three carbon atoms on a reduced basis.

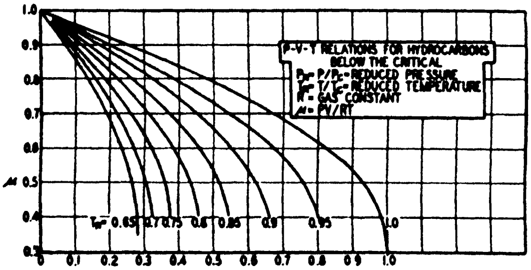

FIG. 337. Correlation of P-V-T Data for Hydrocarbons at Temperatures Below Critical. (W. K. Lewis)

Courtesy Industrial and Engineering Chemistry

The curves in Figs. 336 and 337 have been prepared by Lewis to indicate this correlation for hydrocarbons above and below the critical conditions, respectively. In these graphs, the values of the deviation from ideality, μ, are plotted against the reduced pressure, P_r, for different values of the reduced temperature, T_r. Lewis has emphasized the advantages in the use of these charts for calculating pressure-volume-temperature relations. This type of chart completely eliminates the necessity for knowledge of the critical volume of the specific compound. Thus, if the critical temperature and pressure are available, and the independent variables T and P are known, the reduced properties can be readily calculated. The value

FIG. 338.—Chart of P-V-T Relationships for Methane, Ethylene and Isopentane. (G. G. Brown, W. K. Lewis and H. C. Weber)

of μ may be interpolated from the curves given in Figs. 336 or 337 and substituted in the equation:

$$PV = N\mu RT$$

(N is the number of moles) to give V, the volume occupied by the gas under the assumed conditions. It should be noted that μ is a dimensionless ratio and is numerically independent of the units of measurement employed, provided they are consistent. The quantity R is the gas constant and should be expressed in whatever units are employed throughout the equation.

Although these curves were derived for pure hydrocarbons, Lewis[208] has also applied them to steam, carbon dioxide and ammonia vapor, and has concluded that

[208] W. K. Lewis, *Ind. Eng. Chem.*, 1936, **28**, 257; *Chemistry and Industry*, **1936**, 123; *Chem. Abs.*, 1936, **30**, 1893; *J. Inst. Pet. Tech.*, 1936, **22**, 146A; *Brit. Chem. Abs.* **B**, 1936, 255.

these curves can be used with reasonable accuracy to approximate the properties of other compounds, even though widely different in type.

Brown, Lewis and Weber[209] have plotted the available data for methane, ethylene and isopentane, as is shown in Fig. 338. From this figure it will be noted that for the lower temperature isotherms, the latter hydrocarbon gives lower values for μ than methane and ethylene, but that this condition is reversed on the higher reduced temperature curves.[210]

FIG. 339.—Ratio of Fugacity to Pressure Plotted Against Reduced Pressure for Various Reduced Temperatures. (W. K. Lewis)

Fugacity. Since the ideal gas laws do not hold at high pressures, similar general relations, such as mass action and liquid-vapor equilibria formulas and other equations involving substances in the vapor state, will also be considerably in error. However, by substituting for the pressure a corrected function of the same dimensions (the so-called fugacity, designated by the symbol f) these equations may still be used.

Lewis[211] has demonstrated that the ratio of the fugacity to the corresponding pressure $\left(\frac{f}{P}\right)$ is a unique function of the reduced temperature and pressure for a group of substances conforming to a single reduced equation of state (as, for instance, the higher hydrocarbons). By graphical integration of Figs. 336 and 337, he obtained a series of curves, as shown in Fig. 339, in which the ratio of $\frac{f}{P}$ is plotted against the reduced pressure for different values of reduced temperature. From the latter chart, the values of the fugacity of any hydrocarbon may be calculated at any pressure, provided the necessary critical constants are available.[212]

ESTIMATION OF THERMAL PROPERTIES

The thermal properties of a large number of substances have been determined experimentally. From the data accumulated in this manner, a number of empirical relations have been deduced which may be employed in estimating the thermal data for hydrocarbons in general, or mixtures of hydrocarbons, such as petroleum fractions, in the absence of any available experimental information.

SPECIFIC HEAT

Vapor State. The vapor phase specific heat determinations of Bahlke and Kay,[213] Weir and Eaton,[214] and Gary, Rubin and Ward[215] on the Mid-Continent crude fractions have been found to be in excellent agreement. To establish a basis for estimating the specific heats of vapors of stocks other than those of the above-mentioned type, Watson and Nelson[216] have modified the equation proposed by Bahlke and Kay, by the insertion of a term involving the characterization factor, to give:

$$C_p = \frac{4.0 - s}{6{,}450} (t + 670) (0.12K - 0.41)$$

where C_p is the specific heat of the vapor, t is the temperature (°F.), s is the specific gravity (60/60°F.) and K is the characterization factor. For Mid-Continent stocks ($K = 11.8$) the correction factor reduces to unity. Fig. 340, prepared by Egloff and Nelson,[217] is a graphical representation of the above equation. The specific heats of Mid-Continent stocks and paraffin gases may be read directly from this graph. (For light stocks, the specific gravity is referred to air as 1 and for heavy stocks it is in terms of the A.P.I. gravity of the liquid).[218] For a stock having a characterization other than 11.8, the correction by which the above value is multiplied to give the specific heat is read from the small inset curve.[219]

FIG. 340.—Chart for Specific Heats of Petroleum Vapors. (G. Egloff and E. F. Nelson)

Liquid State. Gaucher[220] has correlated the available data on the specific heats of pure hydrocarbons in the liquid state by means of the equation:

$$C_p = 0.6230 - 0.0187 \frac{\sqrt{T}}{\sqrt{s^3}} + 0.000355\frac{T}{s^3} + 0.00045(t - 32)$$

or in terms of the characterization factor:

$$C_p = 1.323 - 0.2005K + 0.0107K^2 + 0.00045(t - 32)$$

where T = boiling point, in degrees Rankine (Fahrenheit, absolute), s = specific gravity (60/60°F.), t = temperature (°F.), C_p = specific heat at t°F. and K = the characterization factor $\left(\frac{\sqrt[3]{T}}{s}\right)$. Either of these equations is said to express the specific heat of pure hydrocarbons with an average deviation of 1.3 per cent and a maximum of 6 per cent on the basis of the available experimental data.

According to Gaucher, the specific heats of liquid petroleum fractions are best represented by the relationship proposed by Watson and Nelson,[221]

$$C_p = [0.6811 - 0.308s + t(0.000815 - 0.000306s)]\,[0.055K + 0.35.]$$

The symbols here are the same as given above. Fig. 341 is a graphical representation of this function. Thus, the values for Mid-Continent fractions (K = 11.8) may be estimated directly from the main chart. For other stocks, this number is multiplied by the correction obtained from the characterization factor as indicated in the inset curve to give the specific heat. According to Watson and Nelson, the above equation may cause a considerable error at conditions near the critical state because of the variation of C_p with pressure. However, this relation is said to be applicable to pressures well above that required to prevent vaporization, but may give results much too low at sub-atmospheric pressure.[222]

HEAT OF VAPORIZATION

Of the numerous methods[223] for estimating latent heats, Watson and Nelson[224] have stated that the equation proposed by Kistyakovskii[225] for pure hydrocarbons:

$$L = \frac{T_B}{M}(7.58 + 4.571 \log T_B)$$

where L = latent heat of vaporization (B.t.u. per lb.), T_B = normal boiling point (degrees Rankine, °R = °F + 460) and M = molecular weight, may be used as an approximation for hydrocarbon mixtures, provided the average molecular weight and boiling point are used. Assuming the applicability of the above equa-

tion, Watson and Nelson have plotted Fig. 342, in terms of the molal average boiling point and the characterization factor or the molecular weight. However, these investigators advocate, whenever possible, the use of the actually determined molecular weights in preference to the characterization factors curves (the latter involve the estimation of the molecular weight from Fig. 328). They state that the data obtained from Fig. 342 are in good agreement with the experimentally obtained values for the latent heat of vaporization obtained by Weir and Eaton[226] on both Mid-Continent and cracked stocks.[227]

HEAT CONTENT

From their experiments on straight run gas oil stocks, Weir and Eaton[228] proposed the equation:

$$H = (215 - 87s) + (0.415 - 0.104s)t + (0.000310 - 0.000078s)t^2$$

where H = total heat above 32°F. (B.t.u. per lb.), s = specific gravity at 60°F. and t = temperature (°F.), for evaluating the total heats of gas oil vapors above 32°F. Gary, Rubin and Ward[229] have arrived at a similar relation for the total heat of liquid gas oil stocks:

$$H = (15s - 27) + (0.7615 - 0.400s)t + (0.000625 - 0.000440s)t^2$$

The latter authorities have plotted these two functions, as shown in Fig. 343, in terms of the A.P.I. gravity of the fractions. Thus, from this chart it is possible to estimate the input heat required to raise an oil of this nature to a given temperature knowing only the gravity. Gary, Rubin and Ward emphasize the fact that this figure should not be used for cracked stocks, as it is impossible to correlate the heat content data of different types of stocks by means of the specific gravity and temperature relations alone.

Effect of Pressure on Heat Content of Hydrocarbon Vapors. A simple means for correcting the heat contents of gases and vapors for the effect of pressure has been proposed by Watson and Nelson.[230] By a combination of the basic thermodynamic equation

$$\left[\frac{\delta H}{\delta P}\right]_T = V - T\left[\frac{\delta V}{\delta T}\right]_P$$

expressing the rate of change of heat content with respect to pressure at constant temperature, and the corrected equation of state

$$PV = \mu RT$$

these workers obtained a relation of the type

$$\frac{\Delta HM}{T} = f(T_r,P_r)$$

where ΔH = change in heat content due to a change in pressure, M = the molecular weight of the fraction, T = absolute temperature (°R.) and $f(T_r,P_r)$ is a function of the reduced temperature and pressure only. Fig. 344, in which the ratio $\frac{\Delta HM}{T}$ is plotted against the reduced pressure and temperature, represents this relationship as introduced by Watson and Nelson. These curves have subsequently been revised by Egloff and Nelson,[231] as shown in Fig. 345. Thus, for a given reduced temperature and pressure, a value of the above ratio is read from the chart. This expression may now be solved for ΔH and the latter quantity subtracted from the heat content at atmospheric pressure to give the corresponding heat content for the vapor at the assumed pressure.[232]

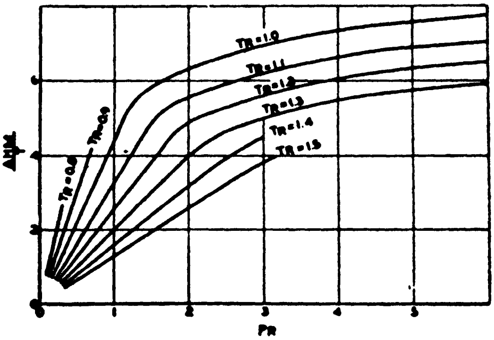

FIG. 344.
Heat Content Correction for Change in Pressure of Hydrocarbon Vapors. (K. M. Watson and E. F. Nelson)

Courtesy Industrial and Engineering Chemistry

Examples of Estimation of Total Heat Content. From the data and charts given on the preceding pages it is possible to obtain the total heat content of either liquid or vapor petroleum fractions over quite a broad range of temperature and pressure. It now remains to illustrate the general principles involved in the use of such information. Egloff and Nelson[233] have suggested several general procedures for problems of this type. For instance, the heat content

---

[230] K. M. Watson and E. F. Nelson, *loc. cit.*

[231] G. Egloff and E. F. Nelson, *Oil and Gas J.*, 1936, 35 (7), 34; *Chem. Abs.*, 1936, 30, 7828. Also "The Modern Cracking Process," Universal Oil Products Co., Chicago, 1936.

[232] According to Watson and Nelson, for ordinary calculations, the difference between heat content at zero and atmospheric pressures may be disregarded.

[233] G. Egloff and E. F. Nelson, *loc. cit.*

FIG. 345.—Revised Chart of Heat Content Corrections for Pressure Change of Hydrocarbon Vapors. (G. Egloff and E. F. Nelson)

may be calculated at atmospheric pressure and the desired temperature and then corrected for the effect of pressure by means of Fig. 345. Or it may be assumed that the fraction is heated as a liquid to its average boiling point, vaporized at that temperature, and superheated as a vapor to the final temperature. (According to these collaborators, the errors introduced by this assumption are ordinarily negligible.) In the case of mixed-phase systems, however, the enthalpies of the liquid and vaporized portions are best treated separately.

As an illustration of the general use of the various charts, that cited by Watson and Nelson[234] using the data of Weir and Eaton[235] obtained for a naphtha fraction (volumetric average boiling point 256°F.) will be considered. The boiling characteristics of this stock, together with the calculated critical temperature and pressure, have already been given[236] and may be summarized as:

Specific gravity	0.7459
A.P.I. gravity	58
Molal average boiling point, °F.	241
Critical temperature, °F.	571
Critical pressure, lbs./sq.in. (absolute)	530

The characterization factor is calculated[237] as

$$K = \frac{(241 + 460)^{1/3}}{0.7459} = 11.9$$

This stock is therefore a typical Mid-Continent fraction, and so either Fig. 340 or 341 may be used directly to obtain the specific heats. From Figs. 328, 329 or 332 the molecular weight may be estimated as 108.

Assuming that it is desired to calculate the heat content above 32°F. for this naphtha in the vapor state at 800°F. and 1000 lbs. per sq. in. (gage pressure), from Fig. 341 the mean specific heat for the liquid between 32 and 241°F. (average boiling point) is obtained at the mean temperature, 137°F., as 0.532. The mean specific heat of the vapor between 241 and 800°F. is estimated from Fig. 340 at the mean temperature (520°F.) as 0.600. The heat of vaporization at 241°F. and $K = 11.8$ may be read from Fig. 342 as 133 B.t.u. per lb. The total heat content at atmospheric pressure, therefore, is given by:[238]

	B.t.u./lb.
Heat of liquid: $0.532(241 - 32) =$	111
Heat of vaporization	133
Heat of vapor: $0.600(800 - 241) =$	335
	579

To evaluate the total heat content at a gage pressure of 1000 lbs. per sq. in., Fig. 344 is used with the following supplemental data:

$$T = 800 + 460 = 1260°\text{F.}$$
$$T_r = 571 + 460 = 1031°\text{R.}$$
$$P_0 = 1000 + 15 = 1015 \text{ lbs. per sq. in. (absolute)}$$

The reduced temperature is, therefore,

$$T_r = 1260/1031 = 1.22$$

and the reduced pressure,

$$P_r = 1015/530 = 1.92$$

---

[235] H. M. Weir and G. L. Eaton, *Ind. Eng. Chem.*, 1932, **24**, 211; *Brit. Chem. Abs.* **B**, 1932, 327; *Chem. Abs.*, 1932, **26**, 1760.

[236] See the section on Estimation of Critical Pressure.

[237] This value may also be obtained by interpolation from Fig. 332.

[238] From experimental data of H. M. Weir and G. L. Eaton, a value of 580 B.t.u. per lb. is given for this stock.

From these values of reduced pressure and temperature the ratio $\frac{\Delta HM}{T}$ is interpolated[289] from Fig. 344 as 4.65, and, therefore,

$$\Delta H = \frac{4.65 \times 1260}{108} = 54 \text{ B.t.u. per lb.}$$

The total heat content at 800°F. and 1000 lbs. per sq. in. is

$$579 - 54 = 525 \text{ B.t.u. per lb.}$$

THERMAL DIAGRAMS FOR HYDROCARBONS

The thermodynamic properties of a substance may be represented graphically in several different manners. Among the most common types of charts in general use that will be considered are enthalpy, temperature-entropy and Mollier diagrams. Each of these series of curves has advantages and special adaptability for different kinds of problems.

ENTHALPY DIAGRAMS

The enthalpy-pressure-temperature relations of hydrocarbons may be very conveniently tabulated in charts of the type of Figs. 346, 347, 348 and 349. In all of these diagrams, the pressure is plotted as ordinate and the temperature as abscissa. Lines of constant enthalpy (heat content or total heat) are represented by straight lines (nearly perpendicular to the temperature axis). In most thermal problems it is not necessary to know the absolute heat content, since only changes

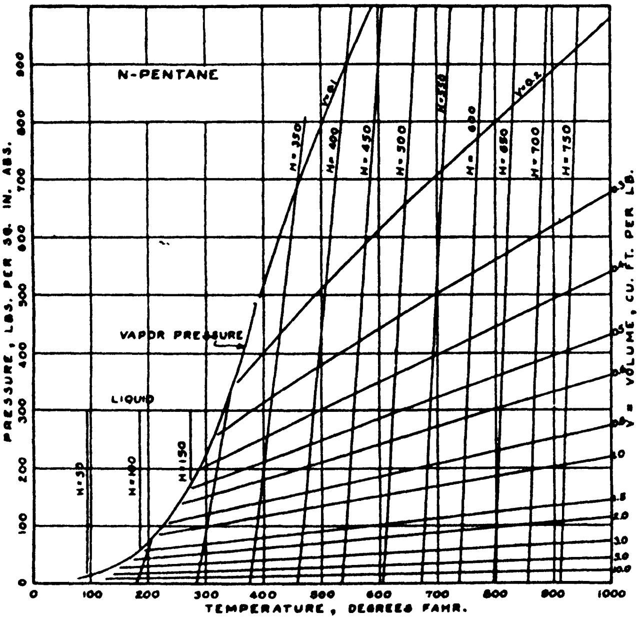

FIG. 346. Enthalpy Diagram for *n*-Pentane. (E. C. Pattee and G. G. Brown)

Courtesy Industrial and Engineering Chemistry

in the relative value are of importance. Therefore, it is arbitrarily assumed in these charts that at one definite set of conditions the heat content may be taken as zero. Ordinarily the datum conditions employed are a standard state (solid, liquid or gas, as the case may be) at 32° F.[240]

---

[289] Fig. 345, based on subsequent data, would give a lower value for this ratio.

The enthalpy diagram for *n*-pentane (see Fig. 346) was determined by Pattee and Brown[241] from experimental data. It is interesting to note the information presented by this chart. The pressure-temperature relation gives the vapor pressure curve. All points to the left of this line refer, therefore, to the liquid phase and those on the right to the vapor phase. In addition to the heat content lines, isochores (constant volume lines) are also included. Thus, from the temperature and pressure of *n*-pentane, it is possible to predict not only the state, but the heat content and volume occupied by the material.

FIG. 347.—Enthalpy-Pressure-Temperature Relationships of Benzene. (J. D. Lindsay and G. G. Brown)

The diagram shown in Fig. 347 was obtained by Lindsay and Brown[242] for benzene. (This chart differs from that of *n*-pentane in that the constant volume lines have been omitted.) Fig. 348 represents the data accumulated by Pattee and Brown[243] for a naphtha fraction[244] and is similar to Fig. 346 in its construction and applicability.

---

[240] Thus, in the case of water, this is standard procedure ordinarily followed, i.e., water at 32° F. and normal pressure is arbitrarily assumed to have a heat content of 0. Following this convention, for conditions below datum, the heat content is regarded as a negative quantity. In petroleum technology, it is often more advantageous to set the datum temperature as 60° F. rather than 32° F. as in the case of water.

[244] The type of naphtha used by these investigators was a so-called varnish maker's and painter's naphtha and had an A.S.T.M. distillation 50 per cent point of about 255°F. Using the method proposed by K. M. Watson and E. F. Nelson (see section on molecular weight) the equivalent hydrocarbon was found to be octane.

From the plots for *n*-pentane and naphtha, Pattee and Brown concluded that for practical purposes, a mixture of hydrocarbons may be treated approximately as a pure compound of the same critical temperature, pressure and molecular weight, as suggested by Watson and Nelson.[245] The former investigators also point out that although the results obtained by these approximations are by no means accurate, the correction due to pressure is so small in comparison with the effect of temperature on the enthalpy that the final result obtained is in all probability sufficiently accurate for most engineering purposes.

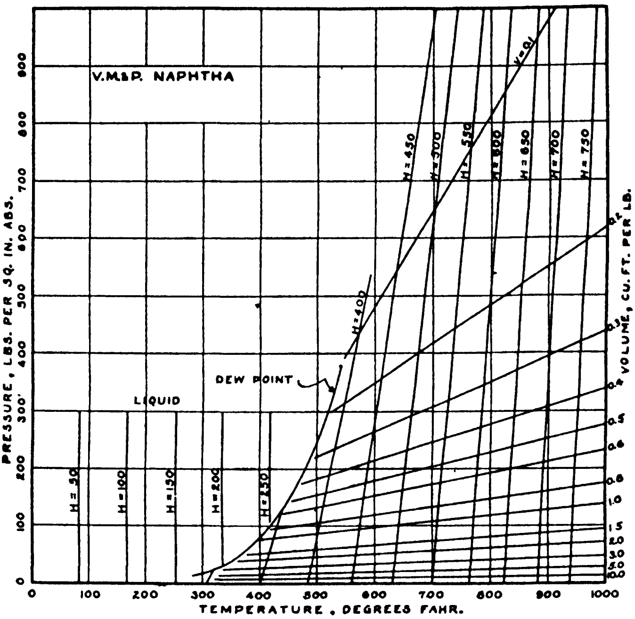

FIG. 348. Enthalpy Diagram for Naphtha Fraction. (E. C. Pattee and G. G. Brown)

Courtesy Industrial and Engineering Chemistry

In Fig. 349 is shown a different type of enthalpy chart, one in which the heat content is plotted against the temperature for parametric values of the pressure. This particular series of curves were determined by Sage, Lacey and Schaafsma[246] for a California crude oil of specific gravity 0.8383 (37.1°A.P.I.) at 60°F. and a molecular weight of 188. In addition to the constant volume lines (indicated by dashes), constant entropy curves are also included on this chart. The double scale has been employed in order to enlarge the isothermal sections. It will be noted that the datum conditions for this graph are saturated liquid at 60°F. and 1 atmosphere. Sage, Lacey and Schaafsma have stated that the entropy-temperature plane is usually preferable for the graphical representation of the thermal properties of a substance. However, in this case, the isothermal changes in entropy are so small compared to the isobaric changes with temperature that the former properties cannot be properly shown in a temperature-entropy scale.

[245] K. M. Watson and E. F. Nelson, *Ind. Eng. Chem.*, 1933, **25**, 880; *Chem. Abs.*, 1933, **27**, 5522; *Brit. Chem. Abs.* **B**, 1933, 995; *J. Inst. Pet. Tech.*, 1933, **19**, 408A.

[246] B. H. Sage, W. N. Lacey and J. G. Schaafsma, *Ind. Eng. Chem.*, 1935, **27**, 162; *J. Inst. Pet. Tech.*, 1935, **21**, 122A; *Brit. Chem. Abs.* **B**, 1935, 886; *Chem. Abs.*, 1935, **29**, 2044.

Sage, Lacey and Schaafsma[247] have shown the applicability of Fig. 349 in estimating the change in heat content of an oil under conditions of adiabatic[248] and isothermal compression. Thus, the frictionless adiabatic compression of the oil follows along a line of constant entropy from the initial to the final state. On the other hand, the isothermal compression is represented by a horizontal path from the initial to the final pressure. In the first instance, the work done by the adiabatic compression is given by the gain in heat content of the fluid or by the graphical evaluation of $\int VdP$ over the constant entropy path. For the isothermal case, however, the gain in heat content is given by Fig. 349, and when the step is frictionless, the heat rejected is determined by ascertaining $T(S_1 - S_2)$ (where the subscripts refer to the initial and final stages, respectively) for the path. The sum of the heat gained and that rejected gives the work done.[249]

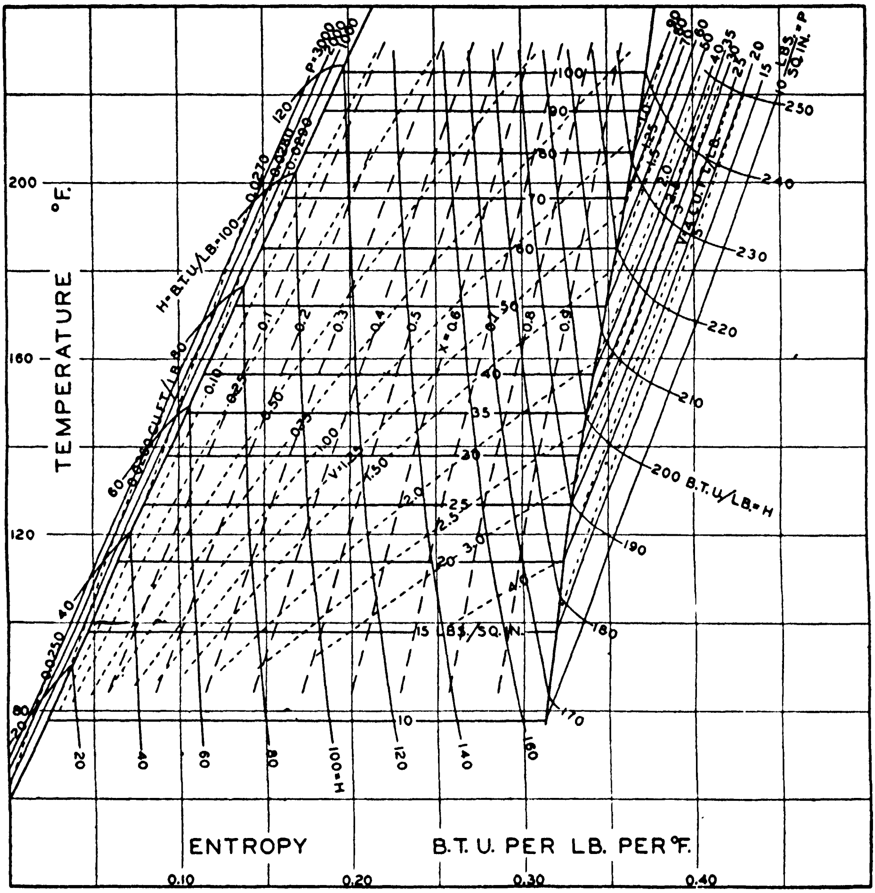
Abs.*, 1935, 29, 2714) tabulated data for the lower hydrocarbons, and also for isobutane (*Refiner*, 1935, 14, 437; *Chem. Abs.*, 1935, 29, 7779). Detailed instructions for the construction of temperature-entropy diagrams and an example (using methane) have been given by J. H. C. Lisman (*Koeltech.*, 1935, 6, 1; *Chem. Abs.*, 1936, 30, 7437).

[251] W. N. Lacey and B. H. Sage, *Oil and Gas J.*, 1934, 33 (26), 86; *Chem. Abs.*, 1935, 29, 585; *J. Inst. Pet. Tech.*, 1935, 21, 10A.

slightly to the center of Fig. 351 (for propane) will be seen the so-called "saturation dome," with the critical point at its apex (the critical temperature for propane is approximately 212°F.). The left-hand side of this line corresponds to the case of liquid propane at its vapor pressure (saturation line.) The right-hand side refers to saturated propane gas. The region beneath the dome applies to equilibrium mixtures containing both liquid and gas phases. The portion of the diagram to the left of the dome describes the behavior of liquid propane at pressures greater



Courtesy *Industrial and Engineering Chemistry*

FIG. 352.—Temperature-Entropy Diagram for *n*-Pentane. (B. H. Sage, W. N. Lacey and J. G. Schaafsma)

than its vapor pressure, and that on the right of the dome relates to information concerning superheated propane gas.

The nearly vertical solid lines (labeled near the top of the figure) are isobars, or lines of constant pressure. Within the saturation dome these lines become nearly horizontal. This is due to the fact that a pure substance undergoes a transition of state (such as from liquid to vapor, or vice versa) at constant temperature and pressure. The short-dash lines indicate values of constant specific volume (cu.ft. per lb. in this case) or isochores. When both liquid and gas phases are present (that is, within the dome), these lines indicate the specific volume of the whole mixture. The long-dash lines (within the dome) meeting at the critical point are lines of constant quality[252] (constant mass fraction of the mixture which is in the gaseous state under the conditions prevailing). The solid lines which slope downward to the right are lines of constant heat content (enthalpy or total heat). Neither the entropies nor enthalpies indicated on this chart are absolute values. Both quantities are based on an arbitrary datum of saturated liquid propane at 60° F.

Fig. 350 represents the temperature-entropy diagram for ethane, as obtained by Walton.[253] The curves for propane, Fig. 351, described previously are the results of investigations conducted by Sage, Schaafsma and Lacey.[254] Fig. 352 for pentane was constructed by Sage, Lacey and Schaafsma[255] from experimental data. (In this instance, the saturation dome has not been included in the figure.)

As an example of the use of these diagrams, the illustration of Lacey and Sage,[256] involving the application of Fig. 351, will be considered. Assume that a sample of propane is at a temperature of 180° F. and occupies a volume per pound of 0.10 cu. ft. By locating the position on the diagram where these two conditions are fulfilled, it will be found that propane exists in the proportions of 0.56 lb. of liquid and 0.44 lb. of gas per lb. of mixture. The pressure is approximately 470 lbs. per sq. in. (absolute), the heat content is 123 B.t.u. per lb. and the entropy is 0.204 B.t.u. per lb. per degree Rankine (Fahrenheit, absolute). This diagram is also useful in problems involving continuous processes, as indicated by Lacey and Sage in the following example. Assume that the above sample of propane passes through a continuous flow system, such that the final conditions find the sample at 80° F. and an absolute pressure of 50 lbs. per sq. in. From the chart it will be found that this hydrocarbon will exist entirely as a gas with a specific volume of 2.55 cu. ft. per lb., a heat content of 164 B.t.u. per lb. and an entropy of 0.347 B.t.u. per lb. per degree Rankine.

To illustrate the further use of this chart, these collaborators assume (arbitrarily) that the last mentioned system consists of the flow of propane through a continuous vertical pipe, 4000 ft. long, and that both the decrease in pressure and the heat gained or lost through the wall are directly proportional to the distance travelled in the pipe. In this case, the useful work of lifting amounts to 4000 ft. lbs. per lb. of propane, which is equivalent to 5.1 B.t.u. per lb. In such a flowing system, the difference between the final and initial heat contents gives the net increase or net decrease in energy in the moving fluid. In the assumed case, the increment is $164 - 123 = 41$ B.t.u. per lb. This net increase in energy, despite the fact that useful work has been done, indicates that energy (in the form of heat) has been added to the fluid through the walls of the pipe. The amount of heat absorbed must then be $41 + 5.1 = 46.1$ B.t.u. per lb.

On the basis of the supposed conditions relating to the change of pressure and heat gained through the walls, it is possible to follow the path of the change occurring during the step. As a result of this, the corresponding values of temperature and entropy may be read from the chart for any stage in the operation. By reading a series of such values and plotting them with entropy as abscissa and the absolute temperature as ordinate, the area below the resulting curve between the initial and final states may be determined, and in this manner the value of the sum of heat absorbed through the walls and the heat developed as the result of friction may be obtained. (The friction results both from turbulence within the fluid and from movement of the mixture relative to the interior pipe wall.) For the above case, Lacey and Sage found this sum to be 81.4 B.t.u. per lb. Since the heat absorbed was 46.1 B.t.u. per lb., the heat developed as a result of friction is

---

[252] Thus, in the case of steam tables, the "quality" is indicative of the percentage of steam actually present under the conditions.

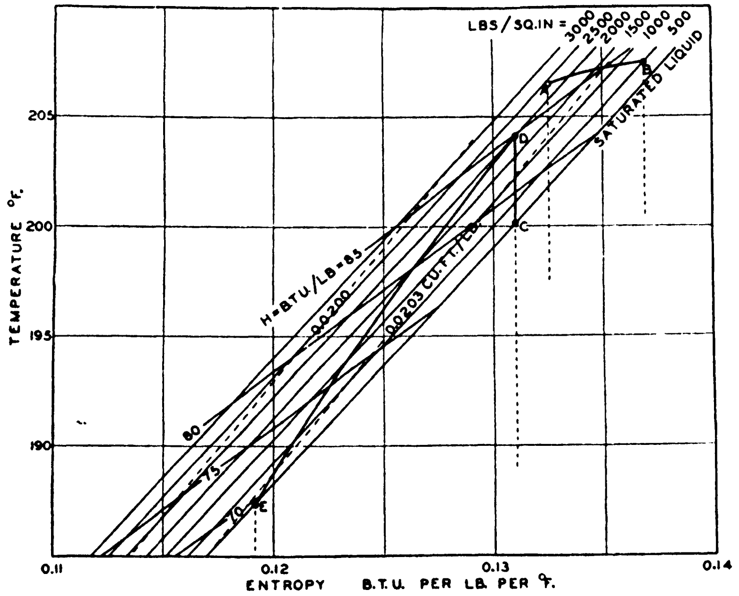
$$81.4 - 46.1 = 35.3 \text{ B.t.u. per lb.}$$

This quantity of heat has been produced at the expense of energy otherwise available for doing useful work. Another way in which the energy is utilized is by increasing the velocity of the moving fluid. The energy required for this purpose is ordinarily quite small, and in the assumed instance would be approximately 0.2 B.t.u. per lb. if the final velocity is taken as 100 ft. per sec.[257]



Courtesy Industrial and Engineering Chemistry

FIG. 353.—Temperature-Entropy Chart for a Crude Oil. (B. H. Sage, W. N. Lacey and J. G. Schaafsma)

Fig. 353 is a temperature-entropy diagram for a California crude oil (37.1° A.P.I. gravity) as determined by Sage, Lacey and Schaafsma[258] from experimental data. These investigators also point out the value of charts of this nature.

---

[257] For other examples, see J. H. Perry, "Chemical Engineers' Handbook," McGraw-Hill Book Co., Inc., New York and London, 1934. W. H. Walker, W. K. Lewis and W. H. McAdams, "Principles of Chemical Engineering," McGraw-Hill Book Co., Inc., New York and London, 1923.

[258] B. H. Sage, W. N. Lacey and J. G. Schaafsma, *Ind. Eng. Chem.*, 1935, 27, 162; *J. Inst. Pet. Tech.*, 1935, 21, 122A; *Brit. Chem. Abs.* B, 1935, 886; *Chem. Abs.*, 1935, 29, 2044.

Thus, the random path *AB* could represent any one of a number of operations. If there is no work done on or by the system, or no change in elevation, the difference in the initial and final heat contents will give the loss of heat from the oil in going from *A* to *B*. The graphically determined value for $\int TdS$ added to the loss in heat content gives the amount of heat produced as the result of friction in the step represented by the path between *A* and *B*. (If the change in elevation or the work done by the oil is known, it can be added to or subtracted from the change in heat content, and the above method can be used to determine the friction.)

The principles outlined by these workers can be illustrated by a specific problem, such as that shown by the path *CDE*. This path may be assumed to be that of a pumping oil well, operating under arbitrarily chosen conditions. Let point *C* represent the condition of the oil at the entrance to the pump cylinder, 4000 ft. below the surface, assuming it to be a liquid at 200.1°F. under the saturation pressure. Point *D* represents the conditions at the outlet of the pump cylinder (corresponding to a pressure of 2000 lbs. per sq. in. after a frictionless adiabatic step, that is, the entropy of the oil at the entrance and outlet of the pump cylinder is the same). The work done in this step is equal to the difference in the initial and final heat content, or 7.5 B.t.u. per lb. of oil. (As a check, the work may be calculated by evaluating $\int VdP$, and is found to be 7.37 B.t.u.) Let point *E* represent the state of the oil at the surface, with a temperature of 187.4°F. and under the corresponding saturation temperature. The path *DE* is arbitrarily chosen to represent the thermodynamic path of the fluid up the pipe line.[259] The difference in enthalpy between *D* and *E* (14.80 B.t.u.) measures the heat lost to the surroundings (in this case, 9.66 B.t.u. per lb. of oil.) The value of $\int TdS$ over the given path from *D* to *E* is found (by graphical integration) to be —7.78 B.t.u. per lb. Then the energy lost as a result of friction during flow is equal to the algebraic sum of $\int TdS$ and the heat lost by the system, and in this instance is equal to 1.88 B.t.u. per lb. of oil.

MOLLIER DIAGRAMS

Mollier diagrams are plotted between heat content as ordinate and entropy as abscissa, and are especially adapted to problems involving flow of fluids. As Walton[260] has pointed out, although on entropy-temperature charts heat quantities are represented by areas, on diagrams of the Mollier type they are shown by line segments. It is also customary to include lines of constant quality, constant superheat, isobars, isotherms and isochores on these depictions.

Fig. 354 represents the Mollier diagram for ethane, as obtained by Walton.[261] The datum temperature for this chart is 332°R. (—128°F.). As an example of the application of the data included in this figure, Walton has considered the following problem. It is desired to determine the condition of the vapor resulting in the expansion (through a valve) of a mixture composed of 95 per cent ethane vapor and 5 per cent ethane liquid at 85.3 lbs. per sq. in. gage pressure to atmospheric pressure (14.8 lbs. per sq. in. absolute). This is an expansion of the Joule-Thomson type, occurring at constant total heat. Thus, from the intersection of the 100 lbs. per sq. in. absolute pressure line and the 95 per cent quality line, the constant heat curve is followed across the diagram to the right until the 14.8 lbs.

---

[259] The thermodynamic properties are dependent only on the initial and final state, and not on the path. However, the exact path is necessary for the evaluation of the friction.

[260] J. S. Walton, *Refiner*, 1935, 14, 440; *Chem. Abs.*, 1935, **29**, 7779. This article should be consulted for an explanation of the manner of derivation of both Mollier and temperature-entropy diagrams from tables of thermodynamic data. Mollier diagrams for ammonia, carbon dioxide, air, ethylene, helium, hydrogen, methane, nitrogen and steam have been given by J. H. Perry, "Chemical Engineers' Handbook," McGraw-Hill Book Co., New York and London, 1934.

[261] J. S. Walton, *loc. cit.*

FIG. 354.—Mollier Diagram for Ethane.

per sq. in. isobar is reached. At this point on the chart it will be seen by interpolation that ethane exists as a superheated vapor at —70° F. and has a superheat of 62° F.

As another example, Walton[262] has calculated the work done in the reversible expansion of 57 lbs. of ethane vapor at 200 lbs. per sq. in. absolute pressure and 475°R. (15°F.) to 30 lbs. per sq. in pressure in an engine, without appreciable loss or gain of heat. Since this is an adiabatic expansion, there will be no change in entropy. The initial heat content of the ethane is read from Fig. 354 as 242.5 B.t.u. per lb. Following down the constant entropy line to the 30 lbs. per sq. in. isobar, the final heat content is given as 206.5 B.t.u. per lb. The available work is, therefore,

$$242.5 - 206.5 = 36 \text{ B.t.u. per lb.}$$

or

$$(36 \times 57) = 2052 \text{ B.t.u.}$$

from the 57 lbs. of ethane. On multiplying this value by the conversion factor, 778, to give foot pounds, the amount of work available is given as

$$(778 \times 2052) = 1{,}596{,}000 \text{ ft. lbs.}$$

The quality of the final mixture may be read by interpolating between the constant quality lines as 98.5 per cent.

As indicated above, the application of thermodynamics to the petroleum field is limited to some extent since the element of reaction time does not enter into this type of calculation. Also, a number of the factors employed are probably subject to considerable error. Nevertheless, in many instances thermodynamic considerations frequently serve to foretell, to a reasonable extent, the probability of a given course of reaction. It is apparent that, as more accurate data come to hand, this phase of the petroleum industry will gradually develop to one of great significance.

Subject Index

A

Abietates, in coating compositions, 543
Abietic acid esters, emulsifying agents for asphalts, 1217
Absorbefacient, definition of, 746
Absorption, infra-red by hydrocarbons, 32
Acenaphthalene, benzene from, 946
—, maleic acid from, 946
Acenaphthene, acenaphthene-quinone from, 955
—, acenaphthylene from, 955
—, dehydrogenation of, 955
—, from propane, 182
—, naphthalic acid from, 955
—, naphthalic anhydride from, 955
—, oxidation of, 946, 955
Acenaphthenequinone, from acenaphthene, 955
Acenaphthenes, from propane, 61
Acenaphthylene, from acenaphthene, 955
—, from natural gas, 240
—, in Thermatomic process, 220
Acetal from ethyl alcohol, 338
Acetaldehyde, acetic acid from, 885, 889
—, acetic anhydride from, 885
—, acetone from, 421-423
—, acetoxime from, 886
—, as insecticide, 891
—, azeotropic mixture with isopropyl alcohol, 369
—, butanol from, 340
—, butyl acetate from, 340
—, butyl propionate from, 340
—, by oxidation of hydrocarbons, 868
—, — of olefins, 893, 896, 897
—, 2-chloro-1,3-butadiene from, 680
—, condensation of, 889

—, removal of iron from, 244
—, silica in, 244
Acetylene carboxylic acids, preparation of, 829
Acetylene diiodide, formation of, 711
Acetylene-ethane, azeotropic mixture of, 30, 1140
Acetylene homologues, effect of lead tetraethyl on, 1019, 1020
Acetylene hydrocarbons, refining with, 719
Acetylene-hydrogen mixtures, chlorination of, 709
Acetylenes, from amylene dibromide, 513
Acetylene tetrachloride, dechlorination of, 710
—, formation of, 709
—, in cleaning compositions, 732
Acetylenic alcohols, preparation of, 724
Acetylenic Grignard reagents, preparation of, 724
Acetyl iodide, reaction with cyclohexene, 611
—, — divinyl ether, 612
—, — furan, 612
—, — thiophene, 611
Acetylketene, heat of formation, 442
Acetylmandelic acetic anhydride, preparation of, 439
2-Acetyl-3-methylbutane, preparation of, 1099
2-Acetyl-1-methylcyclopentane, formation of, 205
2-Acetylpentane, preparation of, 444, 1099
Acetylphthalimide, acetone from, 423
Acetylsalicylic acetic anhydride, preparation of, 439
Acid anhydrides, condensation with conjugated diolefins, 687, 688, 689, 690
—, from ethylene glycol esters, 540
—, from paraffin wax, 971
—, reaction with aldehydes, 885
Acidation, of oil wells, 9
Acid halides, reaction with olefins, 609-614
Acidic oxides, catalysts, reaction of olefins and carbon monoxide, 625, 626
Acidity, determination of, 1166, 1167
Acidosis, effect of ethylene on, 1260, 1261
Acids, aliphatic, sulphates from, 1086
—, as demulsifying agents, 969, 1075
—, by aquolysis, 131
—, by oxidation of petroleum, 962, 964-966
—, catalyst, ethylene oxide-hydrogen sulphide reaction, 564
—, —, polymerization of aldehydes, 886
—, condensation with conjugated diolefins, 688, 690, 691
—, decolorizing with clay, 976, 977
—, effect on stability of naphthenes, 937
—, esterification of, 314

Acids, formation in gasoline, 922
—, from alcohols, 1050, 1052
—, from butane, 874
—, from carbon monoxide and hydrogen, 1223, 1244, 1245
—, from cyanohydrins, 886

—, from oxidation of olefins, 553
—, from oxidation of transformer oil, 935
—, from paraffin wax, 843, 865, 1255
—, from pentane, 859
—, from petroleum ether, 854
—, from propane, 862, 863
—, from still vapors, 1047
—, gasoline-soluble, from ceresins, 975
—, in co-polymerization of chloroprene, 681, 682
—, in gasoline, 908
—, in gum formation, 921
—, in pressure distillates, 1104
—, oxidation of, 852
—, plastics from, 969
—, removal of, from gasoline, 1047
—, separation by acetic acid, 977
—, — alkali bases, 976
—, — alkali carbonate, 975
—, — ammonia, 976, 977
—, — benzene, 967, 968
—, — benzine, 967, 968, 975
—, — calcium hydroxide, 976
—, — calcium hypochlorite, 968
—, — fractional crystallization, 959
—, — fractional distillation, 958, 960, 977
—, — gasoline, 976
—, — hydrogenation, 975, 976
—, — isopropyl alcohol, 975
—, — lime, 967
—, — methyl alcohol, 975, 977
—, — oxidation, 960
—, — phosphoric acids, 977
—, — pyridine, 977
—, — sulphur dioxide, 967, 977
—, — trichloroethylene, 967, 968
—, treatment of gasoline with, 927
—, use in lubricants, 968
—, — rubber vulcanization, 969
—, wetting agents from, 1076
Acid sludge, hydrolysis of, 486
—, reaction with olefins, 669
Acrolein, for solvent extraction, 43
—, from dibromocyclopropane, 762
—, from glycerol, 878
Acrylic acid, from ethylene chlorohydrin, 527
Acrylic acid esters, polymers of, 527
Acrylonitrile, reaction with monoethanolamine, 569
Actinic light, action on motor fuels, 268
—, effect on color stability of fuels, 926
—, use in amylene chlorination, 511
—, — butane chlorination, 752
—, — butene di-iodide synthesis, 511
Actinic rays, use in propane chlorination, 750
Activated aluminum silicate, use in cracking, 128
Activated carbon, catalyst, acetone from acetic acid, 423
—, —, esterification of ethylene glycol, 540
—, —, polymerization of olefins, 171
—, —, pyrolysis of methane, 169
—, use in clarifying wines, 232
Activated charcoal, catalyst, reaction of monovinylacetylene and hydrogen chloride, 680
—, —, esterification of propene, 307
—, —, trimethylacetic acid from acetone, 432
Activated fuller's earth, use in progressive catalysis, 114
Activation energies, for free radicals from hydrocarbons, 51
Activation-energy, of hydrogen halides, 301
—, of triphenylmethyl chloride, 826
Activity, definition of, 1296
Acylaminophenols, antioxidants for gasoline, 916
Acyl urea, stabilization of carbon tetrachloride, 730, 731
Adamantane, isolation from crude oil, 35
Adhesion energies, of asphalts, 1213
Adiabatic transformation, definition of, 1335
Adipic acid, alkoxyalkyl esters, as plasticizers, 544
—, from cyclohexanone, 450
—, from cyclohexene, 895
—, from nitrocylohexane, 1093
Adipic anhydride, antioxidant for transformer oil, 941
Adsorbent carbon, production of, 227
Adsorbent clays, desulphurizing agents, 489
Adsorbent silicates, use in cracking, 129
Adsorbents, use of in refining, 31
Adsorption, of hydrocarbons by silica gel, 31
Adsorption agent, fuller's earth as, 1109
Adsorption agent, gumbrin as, 1109
Adsorptive catalysts, in refining of gasoline, 135
Aerobacter, in fermentation of sucrose, 547
Aerogel, definition of, 446
Aetox gas, definition of, 556
Agar agar, in asphalt emulsions, 1219
Air, absorption by mineral oil, 939
—, effect on hydrogen bromide-allyl bromide reaction, 315
—, — hydrogen bromide-undecenoic acid reaction, 318
—, — hydrogen bromide-vinyl bromide reaction, 315
—, — polymerization of olefins, 661, 672
—, — voltolization, 261
—, ozonized, use in drying oil preparation, 1054
Albuminous substances, in crude oil, 12
Alcoholates, reaction with alkyl halides, 825
—, — aralkyl halides, 825
Alcohol-benzol-gasoline blends, as motor fuels, 1038
Alcohol-gasoline blends, as motor fuels, 1034-1039
—, octane number of, 1251
Alcohols, acetylation by ketene, 438
—, acids from, 1052
—, action of electric discharges on, 262
—, aldehydes from, 399, 844
—, as blending agents, 1035
—, as extraction agents, 972
—, as plasticizing agents, 1112
—, butadiene from, 676, 677
—, by aquolysis, 131
—, by reduction of carbon monoxide, 1049, 1223, 1244, 1251, 1252, 1303-1305
—, combustion of, 999
—, condensation of, 341
—, — with phenols, 402, 403
—, conversion to higher alcohols, 341
—, cyclopentadiene from, 676
—, decomposition of, catalyst for, 155
—, decrease of induction period by, 909
—, dehydration of, 394, 399, 406, 558, 1051, 1052
—, drying agents for, 407
—, esterification of, 1080, 1081, 1118-1120
—, estimation, in blended fuels, 1185
—, ethers from, 406, 579
—, extractants for asphalts, 1202
—, formals from, 889
—, free energy of formation, 1294, 1295

—, in mineral oil, 543
Aluminum sulphate, as antioxidant, 914
—, by-product, hydrolysis of isopropyl sulphates, 364
—, catalyst, esterification of propene, 308
—, —, ether from ethyl alcohol, 331
—, —, hydration of ethylene, 283, 289, 290
—, in insecticides, 1112
Aluminum sulphide, desulphurizing agent, 489
Aluminum sulphonate, properties of, 1067
Aluminum tellurides, catalysts, dehydrogenation of alcohols, 419
Aluminum vanadate, catalyst, decarboxylation of esters, 952
—, —, phthalic anhydride-carbon monoxide reaction, 950
Alundum, use in pyrolysis, 167
Amine-olefin method, for structure of naphthenic acids, 1104, 1111
Amines, addition to cracked distillates, 135
—, as antioxidants, 915, 927
—, catalysts, condensation of sulphonic acids and aldehydes, 1081
—, —, polymerization of aldehydes, 889
—, —, — olefins, 672
—, color stabilizers, 926
—, cracking of, 158
—, critical oxidation potential of, 920
—, emulsifying agents from, 891
—, extraction agents, 44, 976
—, for hydrogen sulphide removal, 458
—, for refining alcohols, 408
—, from acetone, 428
—, from ammonia and olefins, 281
—, from chlorohydrins, 524
—, from nitrocycloparaffins, 1095
—, inhibitors, polymerization of chloroprene, 681
—, —, tetralin autoxidation, 906
—, reaction with acetone, 428
—, — alkyl halides, 808
—, — cyclohexanol, 614
—, — diolefins, 698
—, — ethyl alcohol, 346, 347
—, — ethylene chlorohydrin, 527
—, — olefins, 614, 615
Amino acids, from nitriles, 886
—, inhibitors, gum formation, 915
Aminoazobenzenes, antioxidants, 917
p-Aminobenzoates, local anesthetic, 1256
p-Aminobiphenyl, preparation of, 787
Aminochrysenes, antioxidants, 918
Amino-diaryl ethers, antioxidants, 938
N-Aminodiethylethanol, reaction with 8-amino-6-methoxyquinoline, 569
—, — α-aminopyridine, 569
—, — aniline, 569
—, — 6-chloro-8-amino-quinoline, 569
N-Aminodiethylpropanol, reaction with 8-amino-6-methoxyquinoline, 569
Amino groups, gum inhibitors, 914
Amino-hydroxy-phenones, antioxidants, 916

5-Amino-2-hydroxytoluene, antioxidant, 916
8-Amino-6-methoxyquinoline, reaction with N-amino-diethylethanol, 569
Aminophenanthrenes, antioxidants, 918
Aminophenols, antioxidants, 916
Amino-phenones, antioxidants, 916
β-*p*-Aminophenylaminoethyl alcohol, preparation of, 560
Aminopicenes, antioxidants, 918
α-Aminopyridine, reaction with N-aminodiethylethanol, 569
8-Amino-1,4,5-trihydroxy naphthalene, antioxidant, 916
Ammonia, affinity for olefins, 162
—, catalyst, condensation of phenols and aldehydes, 890
—, —, polymerization of dichlorobutenes, 685
—, color stabilizer for fuels, 926
—, desulphurizing agent, 489
—, effect on Kogasin synthesis, 1236
—, estimation in gases, 1127
—, for fractionation of olefins, 162
—, for hydrogen sulphide removal, 459
—, for hydrolysis of alkyl sulphates, 394, 396
—, for separation of acids, 976, 977
—, from decomposition of ethanolamines, 570
—, from nitric oxide-paraffin reaction, 1091
—, ignition temperature of, 987
—, in asphalt manufacture, 1206
—, in preparation of resins, 216
—, in refining of sulphonates, 1072, 1073
—, inflammability limits of, 980
—, liquefied, for absorption of acetylene, 169
—, pressure-volume-temperature relations, 1321, 1322
—, reaction with acetone, 428
—, — acetylene, 719
—, — aldehydes, 885
—, — alkyl halides, 804, 808
—, — chlorobenzene, 786, 787
—, — *m*-cresol, 788
—, — dichloroethane, 808, 809
—, — β,β′-dihalogenodiethyl ethers, 583
—, — di-iodofluoromethane, 737
—, — ethylene dichloride, 497
—, — methane, 280, 281
—, — olefins, 281, 614, 615
—, — olefin oxides, 567, 585, 587
—, — pentanes, 810
—, — trichloroacetyl glycol, 541
—, — wax acids, 979
—, use in aquolysis, 132
—, — cracking, 614
—, — estimation of sulphur, 1162
Ammoniacal silver, reaction with aldehydes, 885
—, silver from, 885
Ammonia-methane mixture, oxidation of, 871
Ammonium chloride, catalyst, hydration of ethylene, 288
—, —, olefin-carbon monoxide reaction, 446
—, —, reaction of monovinylacetylene and hydrochloric acid, 680
—, desulphurizing agent, 490
—, use in estimation of sulphur, 1162
—, — fermentation of sucrose, 547
Ammonium cyanide, nitriles from, 886
—, reaction with aldehydes, 886
Ammonium halides, catalysts, reaction of carbon monoxide and olefins, 626
Ammonium hydroxide, dechlorinating agent, 805
—, reaction with *o*-dichlorobenzene, 787
—, — nitromethane, 1096
Ammonium naphthenate, as coagulating agent, 1116
—, as demulsifying agent, 1116
Ammonium nitrate, catalyst, ammonia-chlorobenzene reaction, 787
—, for estimation of sulphur, 1161
Ammonium phosphotungstate, catalyst, hydration of ethylene, 288
Ammonium phthalate, phthalimide from, 958
Ammonium salts, emulsifying agents for asphalts, 1218
Ammonium sulphate, from sulphuric acid, 320
—, in cleaning agents, 1112
—, in tanning agents, 1078
Ammonium sulphide, as reducing agent, 1094
—, sulphur extraction with, 461
Ammonium sulphite, reaction with ethyl iodide, 819
—, removal of hydrogen sulphide by, 459
Ammonium sulphonate, as soap, 1069
Ammonium thiocyanate, in synthetic resins, 890
Ammonium thiosulphate, reaction with *n*-dodecyl iodide, 829
Ammonium tungstate, catalyst, hydration of acetylene, 712
Ammonolysis, of ethyl chloride, 808
Amyl acetate, in motor fuels, 1039
—, in rubber cement, 374
sec-Amyl acetate, ketene from, 437
ter-Amyl acetate, from isoamylene, 312
Amylacetylene, formation of, 722
ter-Amyl acid sulphate, hydrolysis of, 394
Amyl alcohol, as extraction agent, 1108, 1188, 1200
—, for absorption of olefins, 163
—, from amyl chloride, 755, 801-803
—, from petroleum ether, 853
—, in motor fuel, 1039
—, precipitation of resins with, 1188
—, reaction with benzene, 411
—, *see also* Pentanol
—, test for, 371
sec-Amyl alcohol, esterification of, 1081
—, from cracked gasoline, 388
—, from pentane, 859
—, reaction with naphthalene, 409
—, — naphthalene sulphonic acid, 409
—, refining ozocerite with, 409
ter-Amyl alcohol, action of sulphuric acid on, 417
—, from pentane, 859
—, from trimethylethylene, 387, 391
—, in refining crude oil, 415
—, pyrolysis of, 410
Amylamine, color stabilizer, 926
—, desulphurizing agent, 488
—, inhibitor of gum formation, 915
Amylbenzene, from phenylcyclopentane, 92
n-Amylbenzene, in gasoline, 144
ter-Amylbenzene, formation of, 411
Amyl bromide, reaction with calcium acetylide, 722
ter-Amyl bromide, hydrolysis of, 803
Amyl chloride, amyl alcohol from, 755
—, amylphenyl methyl ketone from, 448
—, from amylene, 511
—, from cracking gas, 302
—, hydrolysis of, 801-803
—, reaction with amyl oleate, 755
—, — calcium acetylide, 722
—, — oil, 812
—, — sodium cyanide, 822
ter-Amyl chloride, formation of, 310
—, pyrolysis of, 807
—, reaction with methyl pyromucate, 818
ter-Amyl chloroacetates, formation of, 313
ter-Amyl nitrate, from trimethylethylene, 623
—, saponification of, 623
Amylcyclohexane, cracking of, 137
Amylene, absorption in sulphuric acid, 310
—, amylene chlorohydrin from, 626
—, amyl ether from, 630
—, as anesthetic, 1263
—, benzoates from, 630
—, combustion of, 1004, 1005
—, from alcohols, 173
—, isopropyl ethylene glycol from, 548
—, pentane from, 630
—, reaction with benzoyl peroxide, 630
Amylene-1, reaction with chlorine, 511
—, — phosphorus pentachloride, 511
Amylene-2, reaction with chlorine, 512
Amylene chlorohydrin, from amylene, 626
Amylene dibromide, bromination of, 513
Amylene dibromide, preparation of, 513
1-Amylene dichloride, in synthesis of oils, 513
—, in dewaxing lubricants, 513
—, in insecticides, 513
—, preparation of, 511
—, *see also* Dichloropentane

ter-Amylenes, *ter*-amyl chloride from, 310
Amyl ether, from amylene, 630
ter-Amyl ethyl sulphide, preparation of, 472
Amyl formate, formation of, 312
Amyl mercaptan, in petroleum, 454
n-Amyl mercaptan, effect on color stability, 454
ter-Amyl nitrate, from trimethylethylene, 623
Amyl nitrite, action on methyl ethyl ketone, 452
—, reaction with trimethylethylene and nitric acid, 621
Amyl oleate, reaction with pentyl chloride, 755
ter-Amylphenol, as plasticizer, 604
—, preparation of, 412, 604
Amylphenyl methyl ketone, preparation of, 448
—, in paint removers, 448
sec-Amyl sulphate, hydrolysis of, 395
n-Amylsulphonic acid, valeric acid from, 1067
ter-Amyltoluene, formation of, 411
Anaerobic bacteria, action on fatty oils, 19
—, — proteins, 19
—, — waxes, 19
Anaerobic fermentation, in petroleum formation, 19, 20
Anesthetic, acetylene as, 1264
—, alkanes as, 1256
—, amylene as, 1263
—, chloroform as, 728
—, cyclohexane as, 1266, 1267
—, cyclopropane as, 1265, 1266, 1267, 1268
—, ethylene as, 1256-1261
—, propene as, 1263
Anethole, methylene ether from, 625
—, reaction with methyl hypobromite, 531
Aniline, as antioxidant, 917
—, as extraction agent, 30, 1205
—, as heat-transfer medium, 194
—, catalyst, co-polymerization of chloroprene, 681, 682
—, —, vinylacetylene-hydrogen sulphide reaction, 709
—, critical solution temperatures with, 1179
—, effect on octane number, 1032, 1033
—, from benzene, 260
—, from phenyl halides, 787, 810
—, in dewaxing oils, 379, 380
—, in motor fuels, 1039
—, in purification of alcohols, 408
—, inhibitor, paraffin oil oxidation, 907
—, reaction with acetylene, 719
—, — N-aminodiethylethanol, 569
—, — *β,β'*-dibromodiethyl ether, 583
—, — *β,β'*-dichloroethyl ether, 528, 583
—, — diketene, 442
—, — ethyl alcohol, 346
—, — ethyl chloride, 808
—, — 3-ethylpentene-2, 615
—, — fluorochloromethanes, 737
—, — 2-methylbutene-2, 615
—, — 3-methylpentene-2, 615
—, — monobromocyclohexane, 772
—, — monochlorocyclohexane, 768
—, — naphthenic acids, 1109
—, — nitrolic acids, 1094
—, — octene, 615
—, — pseudonitroles, 1094
—, — sulphonic acids, 1068
—, separation of sulphonates, 1072
—, stabilizing carbon tetrachloride, 733
Aniline black printing, use of triethanolamine in, 577
Aniline equivalent, definition of, 1024
—, knock rating by, 1024, 1025
Aniline hydrochloride, reaction with styrene, 614
Aniline point, characterization factor from, 1309
—, determination of, 30, 1150
Anisole, extraction of alcohols with, 360
—, reaction with isopropyl alcohol, 403
Anisotropic substance, definition of, 755
Anisyl alcohol, preparation of, 958
Anthracene, alkylated, from tars, 40
—, alkylation of, 595, 596
—, anthraquinone from, 952-954
—, antioxidant for gasoline, 916, 918, 927
—, by polymerization of cracking gas, 646
—, by pyrolysis of natural gas, 183
Anthracene, from benzene, 957
—, from 2,6-dimethylanthracene, 96
—, from ethylene, 77, 186
—, from isobutene, 85
—, from methane, 179, 180
—, from propane, 61
—, from sulphur-acetylene reaction, 720
—, from tars, 40
—, in acetylene black, 244
—, in petroleum coke, 145
—, oxidation of, 952-954
—, reaction with isoamyl chloride, 827
—, synthesis of coloring matter from, 215
—, synthetic oils from, 212
Anthracite, hydrogen from, 223
Anthranilic acid, color stabilizer, 926
Anthraquinone, cataylst, oxidation of toluene, 949
—, —, chlorination of benzene, 778
—, from anthracene, 952-954
—, reduction to anthranol, 570
Antiknock compounds, effect on ignition temperatures, 996
—, for gasoline, 1013, 1016-1022
Antiknock rating, relationship to structure of hydrocarbon, 141
Antiknock value, effect of peroxides, 924
Antimony, alloys of, in cracking, 112
—, catalyst, bromination of benzene, 790, 791
—, —, chlorination of acetylene, 743
—, —, dehydrogenation of paraffins, 158
—, —, oxidation of ethylene, 552
—, inhibitor, ethylene from methane, 54
—, —, formation of carbon, 191
Antimony chloride, catalyst, alkylation of phenols, 605
—, —, chlorination of ethylene, 495
—, —, — propene, 506
—, —, in cracking, 112
—, reaction with paraffins, 1102
Antimony chlorides, catalysts, bromination of toluene, 795
Antimony dichlorotrifluoride, catalyst, fluorination of carbon tetrachloride, 733, 734
Antimony fluorochlorides, catalysts, in fluorination, 735, 736
Antimonyl tartrate, corrosion inhibitor, 375
Antimony oxide, catalyst, oxidation of aromatics, 942
—, —, — olefins, 553
—, for hydrogen sulphide removal, 458
Antimony pentachloride, catalyst, chlorination of hexane, 757
—, —, — methane, 726
—, —, fluorination of benzene, 792
—, —, — carbon disulphide, 737
—, —, — carbon tetrachloride, 733-736
—, —, — paraffin wax, 759
—, —, — trichloroethane, 747
—, —, polymerization of isobutene, 204
—, —, — styrene, 647
—, for identification of paraffins, 31, 32
—, reaction with gasoline, 32, 1243
Antimony salts, catalyst, fluorination of carbon tetrachloride, 736, 737
Antimony trichloride, catalyst, chlorination of benzene, 778
—, —, condensation of cyclohexane, 205
—, —, esterification of olefins, 302
—, —, in fluorination, 735
—, reaction with hexachloroethane, 748
Antimony trifluoride, catalyst, fluorination of paraffin wax, 759
—, reaction with carbon tetrachloride, 733, 734, 736
—, — methylene chloride, 734
—, trichlorofluoromethane from, 734
Antioxidants, effect on allyl bromide-hydrogen bromide reaction, 315
—, evaluation of, 919, 920
—, for cyclohexene, 907
—, for fats, 914
—, for gasoline, 912, 914-919, 927
—, for hydrogenated oils, 914
—, for paraffin oils, 907
—, for rubber, 855

Antioxidants, for transformer oil, 941
—, for white oils, 937, 940
—, from alkylated phenols, 604
—, natural, in gasoline, 927
—, preparation from lead tetra-alkyls, 823
—, — sulphur, 486
—, reactions with sulphuric acid, 919
—, solvents for, 919
Aqueous content, of crude oil, 10
Aquolization, process of, 131
—, use of ammonia in, 132
—, — magnesium chloride in, 133
—, of emulsions, 133
Aralkyl halides, fluorides from, 735
—, reaction with alcoholates, 825
Aralkyl thiocarbonates, preparation of, 487
Argon, depressant, decomposition of ethylene oxide, 554
—, effect on acetylene polymerization, 267
—, — ignition temperature, 997, 998
—, — inflammability limits, 984, 985
—, — knocking, 1011, 1012
—, — polymerization of butadiene, 650
—, estimation of, 1147, 1148
Argon-nitrogen ratio, in natural gas, 22
Aromatic acids, hydroxy, reaction with olefins, 607
Aromatic alcohols, stabilized by triethanolamine, 577
Aromatic aldehydes, reaction with ketene, 438
Aromatic amines, from chlorobenzenes, 782
Aromatic compounds, extraction of, 30
—, in kerosene, 36
Aromatic hydrocarbons, bromination of, 31
—, separation from gasolines, 30
—, separation from naphthenes, 31
—, separation from paraffins, 31
—, solvents for, 30
Aromaticity, of lubricating oils, 44
Aromatics, action of corona discharge on, 260
—, — silent discharge on, 210, 259, 260
—, aniline equivalents of, 1024
—, antiknock qualities of, 141, 1016
—, by hydrogenation of paraffin wax, 179-181
—, by pyrolysis of gas oil, 178
—, — natural gas, 182, 183
—, — petroleum distillates, 177, 178
—, characterization factor of, 1307
—, combustion of, 999
—, dealkylation of, 208
—, effect of lead tetraethyl on, 1019
—, effect on knock rating, 1024, 1025
—, entropy of formation, 1284-1286
—, estimation, by nitration, 1154
—, —, by oxidation, 1155
—, —, by sulphonation, 1154
—, —, with trinitrophenol, 1154, 1155
—, factors influencing yield of, 188
—, formation of coke from, 109
—, free energy of formation, 1284-1286
—, from acetylene, 89
—, from aliphatic hydrocarbons, 73, 188, 189
—, from asphalt-base spindle oil, 36
—, from butane, 181, 190
—, from carbon monoxide and hydrogen, 1243
—, from cyclohexane hydrocarbons, 178
—, from cycloparaffins, 185, 186, 196
—, from ethyl alcohol, 342
—, from ethylene, 77, 185, 636-639
—, from Gasol, 1255
—, from hydroaromatics, 33
—, from Kogasin, 1252
—, from methane, 179, 180, 181
—, from naphtha oxidation, 876
—, from naphthalene, 36
—, from naphthenes, 843
—, from olefins, 184, 185, 190, 646
—, from paraffins, 141, 186, 187
—, from phenanthrene, 37
—, from pinene, 88
—, from propane, 60, 181, 182
—, from propene, 639
—, heat of formation, 1284-1286
—, improvement of gasolines by, 135
Aromatics, in gasoline, 28, 32, 143
—, —, estimation of, 1149, 1150
—, in petroleum, 13, 17, 31, 32, 1149
—, molal entropy of, 1284-1286
—, —, effect of structure on, 1289, 1290
—, nitration of, 1096, 1154
—, octane numbers of, 1028
—, olefins from, 148
—, oxidation of, 942-961, 1155
—, peroxides from, 922
—, pyrolysis of, 95, 96, 148
—, reaction with carbon monoxide, 1099
—, — chlorinated Kogasin, 1253, 1254
—, — chlorosulphonic acid and naphthenic acids, 1118
—, — ethylene oxide, 563
—, — halogenated olefins, 592, 593
—, — Kattwinkel's reagent, 1150
—, — olefins, 591-598
—, separation, by sulphuric acid, 1081
—, —, with silica gel, 1155
—, stability, effect of structure on, 1285
—, sulphonation of, 1154
—, γ-sulphonic acids from, 1065
—, thermal stability of, 95, 101, 108
—, voltolization of, 261
Arsenic, acid salts, catalysts, reaction of olefins and carbon monoxide, 626
—, catalyst, dehydrogenation of hydrocarbons, 158
—, —, preparation of ethylene oxide, 552
Arsenic acid, catalyst, oxidation of ethylene, 894
—, —, carbon monoxide-methyl alcohol reaction, 1050
Arsenic chloride, catalyst, polymerization of isobutene, 204
Arsenic oxide, catalyst, olefin oxidation, 553
—, for hydrogen sulphide removal, 458
Arsenic trichloride, catalyst, condensation of cyclohexane, 205
—, reaction with cyclohexane, 1102
—, — dioxane, 580
Arsenic trifluoride, catalyst, polymerization of isobutene, 642
Arsenic trioxide, antioxidant, cyclohexene, 907
Arsenious acid, in oxidation of paraffin wax, 973
—, reaction with ethylene dibromide, 505
—, — polyglycols, 545
Aryl amines, condensation with conjugated diolefins, 691
Aryl-amino-naphthalenes, as antioxidants, 918
Aryl arsine oxides, as antioxidants, 918
Aryl cyanamides, for stabilizing carbon tetrachloride, 730
β-Arylethyl alcohols, formation of, 563
Aryl halides, condensation with conjugated diolefins, 691, 693, 694
Aryl stibine oxides, as antioxidants, 918
Aryl sulphonic acids, for refining gasoline, 930
Asbestos, in production of carbon black, 240
Asbestos, platinized, dehydrogenation catalyst, 1150
Ascaridole, definition of, 316
—, effect on hydrogen bromide-isobutene reaction, 317
—, — pentene-2-hydrogen bromide reaction, 318
—, — propene-hydrogen bromide reaction, 316
Ascoloy, catalyst, pyrolysis of olefins, 76
Ash, from petroleum, 46
—, —, composition, 48
Aspergillus niger, action on glycols, 549
Asphalt, acetone solvent for, 434
—, adhesion energy of, 1213
—, adsorption by bleaching earths, 1155
—, as colloidal system, 1195, 1196, 1197, 1198
—, asphaltogenic acids from, 1194

Benzoyl persulphide, preparation of, 480
Benzyl acetate, from benzyl chloride, 794
Benzylacetylene, from phenylallene, 807
Benzyl alcohol, as antiknock, 1017
—, benzoic acid from, 851
—, from benzaldehyde, 958
—, oxidation of, 851
—, solvent properties of, 1179
5-Benzylamino-2-cresol, antioxidant for gasoline, 916
Benzylaminophenol, as antioxidant, 913, 916
Benzyl bromide, from toluene, 795
Benzyl chloride, benzaldehyde from, 957
—, benzoic acid from, 957
—, benzyl acetate from, 794
—, corrosion inhibitor, 794
—, from toluene, 793, 794
—, oxidation of, 957

Benzyl chloride, reaction with acetic anhydride, 794
—, — ethylene glycol, 543
—, — sodium acetate, 794
Benzyl-2-chlorophenyl ketone, benzaldehyde from, 452
Benzyl disulphide, antioxidant for transformer oil, 941
Benzylidene-amino-phenol, antioxidant for gasoline, 916
Benzyl mercaptan, reaction with carbon disulphide, 487
Benzylmethylaminophenol, antioxidant for gasoline, 916
Benzylpyridinium chloride, catalyst, preparation of cellulose derivatives, 588
Benzyl sulphide, corrosion inhibitor, 486
Beryllium bromide, catalyst, bromination of benzene, 791
Beryllium chloride, catalyst, alkylation of aromatics, 596
—, —, polymerization of isobutene, 204, 642
Beryllium compounds, catalysts, oxidation of alcohols, 1051
Beryllium oxide, catalyst, decarboxylation of phthalic anhydride, 950
—, —, methane-steam reaction, 279
—, —, oxidation of aromatics, 942
—, —, reduction of carbon monoxide, 1228
Beryllium phosphate, catalyst, hydration of ethylene, 287
—, —, hydration of propene, 293
Beryllium sulphate, promoter, hydration of ethylene, 283
Biacetyl, flavoring agent, 708
—, from 2,3-butene glycol, 548
—, from methyl ethyl ketone, 452
—, from vinylacetylene, 708
Bibenzyl, from benzene and acetylene, 718
—, from benzene and ethylene oxide, 563
—, from stilbene, 207
—, molal entropy, 1289
Bichloride of mercury, *see* Mercuric chloride
Bicyclic naphthene hydrocarbons, derivatives of, 10
Bicyclohexyl, cracking of, 137
—, preparation of, 205, 767
Biphenyl, as heat-transfer medium, 28, 191, 193, 194, 420
—, from benzene, 95, 191, 206, 207, 259, 260
—, in lubricants, 194
—, in motor fuel, 1039
—, molal entropy, 1289
—, reaction with chlorinated paraffin wax, 817
Biphenyl homologues, viscosity of, 38
Biphenylene, from benzene, 259
Bis-(2-chloroethyl) ether, as dewaxing agent, 434
Bis-(β-methoxyethyl) methylene ether, preparation of, 582
Bismuth, catalyst, bromination of benzene, 790, 791
—, —, isopropyl alcohol from propene, 360
—, —, oxidation of ethylene, 552
Bismuth bromide, catalyst, esterification of alcohol, 345
—, —, — propene, 308
Bismuth chloride, catalyst, chlorination of ethylene, 495
—, —, — propene, 506
—, —, esterification of alcohol, 345
—, —, — olefins, 301, 302, 306, 311, 316
—, —, reaction of olefins and chloroethers, 613
—, —, — propene and iodine, 506
Bismuth halides, catalysts, dehydrogenation of hydrocarbons, 158
—, —, reaction of carbon monoxide and olefins, 625, 626
Bismuth ions, catalysts, nitration of toluene, 954
Bismuth oxide, catalyst, decarboxylation of phthalic anhydride, 951
—, —, oxidation of aromatics, 942, 950
—, —, reaction of benzyl chloride and acetic anhydride, 794
—, effect on ignition temperature, 1000
Bismuth phosphate, catalyst, isopropyl acetate from propene, 308
Bismuth salts, promoters, oxidation of toluene, 950
Bismuth sulphate, catalyst, isopropyl acetate from propene, 308
Bismuthyl chloride, catalyst, ethyl alcohol-hydrogen chloride reaction, 345
Bisnitrosates, from olefins, 620
Bisulphates, catalysts, dimerization of ethylene oxide, 579
Bituminous emulsions, coagulation of, 1116
Bivinyl, *see* Butadiene
Black kontakt, as demulsifying agent, 1075
—, definition of, 1075
Bleaching agents, sulphuric esters of ethanolamines as, 578
Bleaching clay, in decolorizing resins, 216
Bleaching earths, catalysts, polymerization of diolefins, 171
—, —, oxidation of methane, 882
—, in asphalt compositions, 1214
—, separation of asphalts in oil, 1155
Bleaching powder, use in purification of acetylene, 170
Blended motor fuels, 1034-1040
Blending agents, for gasoline-alcohol-benzol blends, 1038
—, for gasoline-alcohol blends, 1035
Blending octane number, definition of, 1025, 1029
—, comparison with octane numbers, 1026
—, knock rating by, 1025-1027
—, of 1-heptene, 1026, 1027
Blood, effect of ethylene on, 1260, 1261
Blood pressure, effect of cyclopropane on, 1265
—, effect of ethylene on, 1261
Blood sugar, effect of ethylene on, 1260, 1261
Blood urea, effect of ethylene on, 1261
Boiling point, critical pressure from, 1314, 1315, 1316
—, heat of vaporization from, 1325, 1327
—, molal average, characterization factor from, 1307, 1309, 1310
—, —, critical pressure from, 1318
—, —, critical temperature from, 1312, 1313
—, —, estimation of, 1308, 1309
—, —, molecular weight from, 1311
—, 50 per cent, critical temperature from, 1311, 1312
Bone charcoal, catalyst, cracking of petroleum, 111
Bone fat, in asphalt emulsions, 1216
Bone grease, reaction with ethylene glycol, 540
Boost pressure, definition of, 1027
Borax, extractant for butadiene, 174
Borates, estimation with isopropyl alcohol, 375
Borax, catalyst, cracking of petroleum, 111
Boric acid, catalyst, oxidation of ethylene, 894
—, —, — paraffin wax, 973
—, —, polymerization of olefins, 634
—, —, pyrolysis of methane, 227
—, corrosion inhibitor, 574
—, reaction with diethylene glycol monoethyl ether, 545
Boric acid salts, catalyst, hydration of ethylene, 288
—, —, reaction of olefins and carbon monoxide, 626
Borneol, as blending agent, 1035
—, dehydrogenation of, 444
Boron, catalyst, pyrolysis of gaseous hydrocarbons, 189
Boron carbide, catalyst, oxidation of toluene, 948
Boron fluoride, as decolorizing agent, 1192
—, as refining agent, 719
—, catalyst, esterification of acids, 314
—, —, — olefins, 308
—, —, — acetylene, 717
—, —, vinylacetylene-alcohol reaction, 706
—, —, vinylacetylene-carboxylic acid reaction, 706
—, —, voltolization, 262
—, *see also* Boron trifluoride
Boron oxide, catalyst, hydrogen-carbon monoxide reaction, 661
—, —, oxidation of aromatics, 942

Boron phosphate, as antiknock, 115

p-*sec*-Butylphenol, from *sec*-butylphenyl ether, 403
ter-Butylphenol, preparation of, 403, 412, 818
o-*ter*-Butylphenol, preparation of, 418
p-*ter*-Butylphenol, preparation of, 403, 418
ter-Butylphenols, utilization of, 818
Butylphenyl ethers, isomerization of, 403
Butyl phthalate, as antiknock, 1017
—, preparation of, 501
N-Butylpiperidines, preparation of, 773
Butyl propionate, from acetaldehyde, 340
ter-Butyl-*sec*-propyl ether, preparation of, 414
n-Butylsulphonic acid, butyric acid from, 1067
ter-Butylsulphuric acid, from isobutene, 308
ter-Butyltoluene, preparation of, 411
p-*ter*-Butyltoluene, reaction with isopropyl chloride, 816
1-Butyne, preparation of, 722
Butyraldehyde, condensation of, 889
—, from butyl alcohol, 878, 880
—, from crotonaldehyde, 889
—, iso-octenyl aldehyde from, 878
—, octyl alcohol from, 889
—, ozonization of, 887
Butyric acid, dipropyl ketone from, 443
—, from *n*-butylsulphonic acid, 1067
—, from carbohydrates, 443
—, from carbon monoxide and hydrogen, 1244
—, from cracked gasoline, 854
—, from paraffin wax, 971
—, solvent for ketene, 437
Butyrolactone, as extraction agent for acetylene, 169

C

Cadmium, catalyst, polymerization of olefins, 665
—, —, pyrolysis of methane, 55
—, —, — olefins, 78
—, —, — paraffins, 159
—, —, reaction of acetylene and amines, 719
—, reaction with trichloroethylene, 711
—, stabilizing agent for ethylene oxide, 554
Cadmium acetate, catalyst, acetylene-acetic acid reaction, 717
Cadmium antimonide, catalyst, dehydrogenation of alcohols, 419
Cadmium arsenide, catalyst, dehydrogenation of alcohols, 419
Cadmium bismuthate, catalyst, dehydrogenation of alcohols, 419
Cadmium bromide, catalyst, propene-acetic acid reaction, 308
Cadmium chloride, catalyst, propene-acetic acid reaction, 308
—, in preparation of 2,3-dialkyldioxanes, 581
Cadmium chromite, catalyst, dehydrogenation of alcohols, 420
Cadmium discresyl, antioxidant for lubricants, 938
Cadmium halides, catalysts, dehydrogenation of hydrocarbons, 158
—, —, fluorination of dichloroethane, 747
—, —, hydration of acetylene, 712
—, —, reaction of olefins and carbon monoxide, 625, 626
Cadmium oxide, catalyst, ethanol-steam reaction, 422
—, —, decarboxylation of phthalic anhydride, 951
—, —, hydration of ethylene, 291
—, —, oxidation of acenaphthene, 946
—, —, — aromatics, 942
—, —, — naphthalene, 946
—, effect on ignition temperatures, 1000
Cadmium phosphate, catalyst, hydration of ethylene, 287, 288, 290
—, —, hydration of propene, 293
—, —, polymerization of olefins, 634
—, —, reaction of ethers and alkyl halides, 345
—, —, — propene and acetic acid, 308
Cadmium phosphide, catalyst, dehydrogenation of secondary alcohols, 419
Cadmium salts, catalysts, hydration of vinylacetylene, 705
—, —, polymerization of olefins, 929
—, —, reaction of acetylene and phenol, 715
—, —, — ethylacetylene and acetic acid, 718
Cadmium selenide, catalyst, dehydrogenation of alcohols, 419

Cadmium sulphate, catalyst, propene-acetic acid reaction, 308
—, —, hydration of ethylene, 283
—, reaction with triethanolamine, 571
Cadmium sulphide, catalyst, pyrolysis of mercaptans, 472, 479
Cadmium telluride, catalyst, dehydrogenation of alcohols, 419
Caesium carbonate, catalyst, condensation of alcohols, 340
Caffeine, extraction with dichloroethane, 745
—, stabilizing agent for tetrachloroethane, 743
Calcium, catalyst, ethers from acetals, 715
—, —, oxidation of paraffins, 874
—, desulphurizing agent, 489
Calcium acetylide, preparation of, 722
—, reaction with diethyl sulphate, 722
Calcium alkylsulphonates, surface tension of, 1066, 1067
Calcium antimonide, catalyst, dehydrogenation of alcohols, 419
Calcium arsenide, catalyst, dehydrogenation of alcohols, 419
Calcium bismuthate, catalyst, dehydrogenation of alcohols, 419
Calcium bisulphide, reaction with vinyl sulphone, 618
Calcium borate, catalyst, ethanol-steam reaction, 422
Calcium boro-phosphate, catalyst, hydration of butenes, 294
—, —, — ethylene, 285
—, —, — propene, 292
Calcium bromide, reaction with diethanolamine, 572
—, — triethanolamine, 572
Calcium butyrate, preparation of, 443
Calcium carbide, reaction with deuterium oxide, 743
Calcium carbonate, catalyst, acetone from ethyl alcohol, 423
—, —, chlorination of trimethylethylene, 513
—, —, cracking of wax acids, 979
—, —, ethanol-steam reaction, 422
—, —, hydration of ethylene, 291
—, —, oxidation of ethyl alcohol, 423
—, —, polymerization of ethylene oxide, 562
—, —, pyrolysis of methane, 218, 227
—, reaction with ethylene dichloride, 533
Calcium caseinate, in insecticides, 1112
Calcium chloride, catalyst, acetylene-hydrogen chloride reaction, 716
—, —, chlorination of propene dichloride, 507
—, —, dechlorination of propyl chloride, 806
—, —, propene-hydrogen chloride reaction, 306
—, dehydration agent for *sec*-butyl alcohol, 404
—, — isopropyl alcohol, 364
—, demulsifying agent, 1105
—, extraction agent for amylene, 173
—, — piperylene, 173
—, in fermentation of sucrose, 547
—, in gas analysis, 1123
—, in purification of napthenic acids, 1109
—, promoter, reduction of carbon monoxide, 1229
—, reaction with isopropyl alcohol, 370
—, — methane, 1102
—, — triethanolamine, 572
—, removal of acetylene with, 170
—, stabilizing agent for asphalt emulsions, 1215, 1218
Calcium compounds, catalysts, acetylene-steam reaction, 714
Calcium dihydrogen phosphate, catalyst, oxidation of ethylene, 894
Calcium fluoride, reaction with carbon tetrachloride, 736, 737
—, — chloroform and silver fluoride, 737
Calcium halides, catalysts, hydration of acetylene, 712
Calcium hydride, catalyst, in cracking, 115
Calcium hydroxide, catalyst, acetone from acetic acid, 423
—, —, chlorination of propene dichloride, 507
—, —, decarboxylation of phthalic anhydride, 950
—, —, hydrolysis of methyl chloride, 796
Calcium hydroxide, dehydration agent for isopropyl alcohol, 365
—, extraction agent for naphthenic acids, 1107
—, — wax acids, 976
Calcium hypochlorite, reaction with diethyl ketone, 453
—, separation of acids with, 968
Calcium iodide, reaction with triethanolamine, 572
Calcium monophosphate, catalyst, reaction of olefins and carbon monoxide, 626
Calcium naphthenate, antioxidant for lubricants, 937
—, catalyst, oxidation of paraffin wax, 971
—, —, — petroleum, 963, 972
—, in inks, 1117
Calcium nitrate, solubility in isopropyl alcohol, 370, 375
Calcium oxide, catalyst, acetone from acetic acid, 423
—, —, chlorination of propene dichloride, 507
—, —, condensation of acetone, 429
—, —, decarboxylation of phthalic anhydride, 950, 951
—, —, dipropyl ketone from *n*-butyl alcohol, 443
—, —, ethylene oxide from ethyl hypochlorite, 551
—, —, in cracking, 128, 137
—, —, oxidation of ethyl alcohol, 423
—, —, polymerization of ethylene oxide, 562
—, —, pyrolysis of oxygenated hydrocarbons, 340
—, —, wax acid-pentaerythritol reaction, 1055
—, dehydration agent for isopropyl alcohol, 364
—, extraction agent for naphthenic acids, 1105
—, in preparation of morpholine, 583
—, promoter, dechlorination of butyl chloride, 806
—, —, in cracking, 112
—, —, methane-steam reaction, 272
—, —, reduction of carbon monoxide, 1240
—, reaction with butene oxide, 590
—, — trichloroacetaldehyde and deuterium oxide, 729
—, refining agent for gasoline, 669
—, solubility in isopropyl alcohol, 375
Calcium phosphate, catalyst, dechlorination of propyl chloride, 805
—, —, ethanol-steam reaction, 422
—, —, hydration of ethylene, 287
—, —, — propene, 292
Calcium phosphides, catalysts, dehydrogenation of alcohols, 419
Calcium rosinate, stabilization of asphalt emulsions, 1217
Calcium selenide, catalyst, dehydrogenation of alcohols, 419
Calcium silicate, catalyst, ethanol-steam reaction, 422
—, —, oxidation of ethanol, 423
Calcium soaps, catalysts, oxidation of paraffin wax, 972
—, in grease, 1079
—, in lubricants, 1079
Calcium sucrate, antioxidant for gasoline, 917
Calcium sulphate, catalyst, ethylene-sulphuric acid reaction, 323
—, —, hydration of propene, 292
—, —, sulphation of propene, 358
Calcium sulphide, reaction with ethylene dichloride, 499
Calcium sulphocyanide, catalyst, esterification of cellulose, 588
Calcium sulphonates, as emulsifying agents, 1074
—, extraction of, 1065
—, in insecticides, 1077, 1078
Calcium telluride, catalyst, dehydrogenation of alcohols, 419
Camphor, antioxidant for gasoline, 918
—, as antiknock, 1017
—, from borneol, 444
—, in motor fuel, 1039
—, in polyprene, 681
—, preparation of, 688
—, reaction with nitric acid, 851, 852
Camphoric acid, antioxidant for gasoline, 918
Camphorone, antioxidant for gasoline, 918
Candle wax, preparation of, 543

Candles, Kogasin in, 1255
—, paraffin wax in, 1255
Caproic acid, formation of, 904
Capryl alcohol, *see* 2-Octanol
Carbazole, alkylation of, 595
Carbenes, action of carbon tetrachloride on, 1196
—, by polymerization of acetylene, 704
—, by pyrolysis of naphthenes, 196
—, definition of, 1193
—, estimation of, 1193
—, from lubricating oil, 855, 932
—, in asphalts, 1193
—, reaction with sulphuric acid, 1193
Carbides, catalysts, oxidation of paraffin wax, 971
Carbitol, in brake fluid mixtures, 578
Carboids, by hydrogenation of shale tar, 1194
—, by oxidation of asphaltenes, 1203
—, estimation of, 1193
—, reaction with sulphuric acid, 1193, 1194
Carbon, adsorption of alcohols, 1075
—, — butadiene, 174
—, — ethylene, 324
—, — naphthenes, 1149, 1150
—, — olefins, 328
—, — paraffins, 1149, 1150
—, — saponifiable acids, 732
—, — saponifiable oils, 732
Carbon, by cracking kerosene, 137
—, — sapropelites, 143
—, — *n*-tetradecane, 1297
—, by electrical decomposition of methane, 253
—, by pyrolysis of benzene, 191
—, — *n*-butane, 64
—, — ethane, 56, 151
—, — *n*-hexane, 71
—, — isobutene, 85
—, — methane, 54, 218-220
—, — natural gas, 220, 228
—, — paraffins, 159, 188
—, — 2-pentene, 87
—, — propane, 61
—, carbon tetrachloride from, 730
—, catalyst, acetic acid from ethyl chloride, 830
—, —, acetylene-hydrogen chloride reaction, 716
—, —, carboxylic acids from olefins, 446
—, —, chlorination of methane, 726
—, —, chlorination of toluene, 793
—, —, condensation of carbon tetrachloride, 731
—, —, dechlorination of tetrachloroethane, 805
—, —, ethanol-steam reaction, 422
—, —, for fluorination, 735, 736
—, —, in cracking, 111, 137
—, —, ketene-hydrogen chloride reaction, 439
—, —, methane-steam reaction, 278
—, —, oxidation of ethylene, 894
—, —, oxidation of petroleum, 964
—, —, polymerization of olefins, 636
—, —, pyrolysis of acetylene, 89
—, —, — benzene, 192
—, —, — hydrocarbons, 158
—, —, — olefins, 158
—, —, — propane, 189
—, coagulation, by sulphonic acids, 1081
—, desulphurizing agent, 1043
—, effect on pyrolysis of 2-butene, 172
—, from petroleum coke, 231
—, in lubricants, 930, 931
—, in purification of phthalic anhydride, 961
—, methane from, 1278
—, promoter, oxidation of toluene, 950
—, —, reaction of benzene and chlorine, 778
—, —, reduction of carbon monoxide, 1228
—, reaction with hydrogen, 168, 1278
—, — methane, 168
—, — sulphur dichloride, 730
Carbonating muds, as emulsifying agents, 1217
Carbon black, absorption of oil, 246
—, adsorptive power, determination, 249, 252
—, —, effect on rubber on, 252
—, ash in, 251
—, color index of, 248
—, color intensity, 246
—, —, effect of compression, 246
—, —, effect of vibration, 246
—, color measurement of, 252
Carbon black, combustion of, 245
—, dispersion of, 248, 1117
—, effect of channel height on, 239
—, — flame structure on, 239
—, effect on curing of rubber, 249
—, electrostatic precipitation of, 222
—, extraction with acetone, 251
—, extraction with benzene, 251
—, from acetylene, 223, 235, 242
—, from butane, 219, 237
—, from carbon monoxide, 229
—, from ethane, 240
—, from gaseous hydrocarbons, 224, 235, 237
—, from gilsonite, 244
—, from methane, 219, 236, 240, 255
—, from natural gas, 23, 220, 222, 236
—, from olefins, 237
—, from petroleum oils, 226, 255
—, from propane, 219, 237, 240
—, from resin, 244
—, from still residues, 244
—, ignition temperature of, 245
—, in clarifying wine, 232
—, in nitrocellulose lacquer, 247
—, in printing ink, 250
—, in rubber, 240, 245, 246, 249, 250
—, oil-absorption index, 248
—, particle size, 249
—, utilization of, 249, 250, 251
—, wetting of, 246
—, X-ray diffraction patterns, 245
Carbon dioxide, carbon monoxide from, 1247
—, deasphalting agent, 45
—, effect on absorptive power of carbon black, 249
—, — acetylene polymerization, 267
—, — combustion, 1004
—, — decomposition of ethylene oxide, 554
—, — gasoline, 924
—, — ignition temperature, 998
—, — inflammability limits, 983, 984, 985
—, — Kogasin synthesis, 1235, 1241, 1242
—, — methane oxidation, 264
—, — osmotic resistance of erythrocytes, 1261
—, — stability of methyl nitrate, 1093
—, estimation in ethylene, 1259, 1260
—, — natural gas, 1123
—, ethylene from, 1241
—, extraction of ethylenediamine with, 497
—, from benzene, 273
—, from carbon monoxide, 277, 278
—, from carbon tetrachloride, 731
—, from cyclohexane, 273
—, from cyclohexene, 273
—, from ethyl acetate, 421
—, from ethyl alcohol, 348, 351, 353
—, from ethylene, 551, 552, 897
—, from hexane, 273
—, from hydrocarbon oils, 131
—, from hydrocarbons, 269
—, from isopropyl alcohol, 371
—, from methane and steam, 270-273
—, from 2-methyl-propene, 622
—, from natural gas, 22, 1121
—, from phenylacetylene, 904
—, from *m*-xylene, 273
—, in crude oil, 10
—, in fumigants, 556
—, methane from, 1241, 1242
—, pressure-volume-temperature relations, 1321, 1322
—, reaction with benzene, 260
—, — coke, 1247
—, — ethylene bromohydrin, 532
—, — ethylene chlorohydrin, 532
—, — ethylene dibromide, 532
—, — ethylene dichloride, 532
—, — dihydronaphthalene, 958
—, — hydrogen, 661
—, — methane, 273-275, 870, 1246
—, — natural gas, 278
—, — phthalic anhydride, 950
—, reduction of, 1247
—, removal with ethanolamines, 574

Carbon disulphide, carbon tetrachloride from, 730
—, catalyst, in cracking, 112
—, —, reaction of ethylene dichloride and sodium polysulphide, 499
—, combustion of, 1003, 1004
—, effect on Kogasin synthesis, 1236
—, from acetylene, 467, 720
—, from carbon tetrachloride, 469
—, from mineral oil, 468
—, ignition temperature of, 987
—, inflammability limits of, 980
—, inhibitor, deposition of carbon, 192
—, oxidation of, 851
—, peptizing agent for asphalts, 1196
—, promoter, reaction of propyl benzene and propionyl chloride, 447
—, reaction with chlorine, 730
—, — hydrogen fluoride and chlorine, 737
—, — nitroparaffins, 1096
—, solvent, asphalt components, 1190, 1193, 1200
Carbonic acid, reaction with hydroxyalkylamines, 569
Carbonit earth, use in refining lignite spirits, 928
Carbon monoxide, acids from, 1223, 1244, 1245
—, alcohols from, 1049, 1223, 1244, 1251, 1252
—, —, free energy change, 1303-1305
—, aldehydes from, 1223, 1244
—, aromatics from, 1243
—, carbon black from, 229
—, catalyst, polymerization of olefins, 636
—, combustion of, 1010
—, Diesel fuel from, 1250
—, effect on chlorination of olefins, 493
—, — decomposition of acetaldehyde, 884
—, — decomposition of ethylene oxide, 554
—, esters from, 1223
—, estimation in ethylene, 1259, 1260
—, estimation in gaseous hydrocarbons, 1124, 1127, 1128, 1133
—, free energy of formation, temperature effect, 1304
—, from butane, 275
—, from carbon dioxide, 274, 1247
—, from coal, 1246
—, from coke, 1247
—, from coke-oven gas, 1246-1248
—, from ethyl alcohol, 347-349, 352, 353
—, from ethylene, 622
—, from ethylene oxide, 554
—, from generator gas, 1246
—, from hydrocarbons, 269
—, from kerosene, 272
—, from ketene, 437
—, from methane, 224, 226, 270 274, 1246
—, from methyl ethyl ketone, 449, 450
—, from petroleum, 17
—, from petroleum gases, 21, 1048
—, from propane, 275
—, from still gases and steam, 229
—, from water, 256
—, from water gas, 1246
—, Gasol from, 1250
—, gasoline from, 1229, 1231, 1235, 1243, 1245, 1247, 1250-1252
—, ignition, 1001
—, —, effect of nitrogen on, 1001, 1002
—, ignition temperature of, 987, 988, 997
—, inflammability limits of, 985
—, ketones from, 1223, 1244
—, Kogasin from, 1223
—, lamp oil from, 1250
—, olefins from, 1223, 1235, 1241-1243
—, oxidation of, effect of temperature on, 850
—, paraffins from, 1223, 1226, 1235, 1236, 1240 1243, 1245, 1250
—, γ-pyrone from, 1244
—, reaction with alcohols, 407, 1041, 1050
—, — aromatics, 949, 957, 1099
—, — hydrogen, 660, 661
—, —, effect of catalysts, 1228-1230
—, —, mechanism, 1224, 1225
—, —, thermodynamics of, 1225-1227
—, — methyl chloride, 727
—, — olefins, 446, 625, 626, 893
—, — paraffins, 1099
Carbon monoxide, reaction with phthalic anhydride, 950
—, — sodium phenolate, 957
—, — steam, 269, 270, 277, 446, 871
—, reduction of, free energy change, 1303-1305
—, removal with cuprous formate solutions, 234
—, — cuprous lactate solutions, 234
—, Synthin from, 1223
—, Synthol from, 1223
—, terpenes from, 1244
—, use in cracking, 115
—, — oxidation of gaseous hydrocarbons, 851, 893
—, — pyrolysis of hydrocarbons, 156
Carbon remover, preparation of, 486
Carbon silicide, use in pyrolysis of methane, 892
Carbon tetrachloride, action on carbenes, 1196
—, adsorption by carbon, 252
—, as heat transfer medium, 510, 949
—, as parasiticide, 733
—, as solvent, 307, 505, 742
—, carbon dioxide from, 731
—, catalyst, in cracking, 114
—, —, oxidation of ethylene, 894
—, —, polymerization of unsaturates, 214
—, chloral from, 731
—, chloro-fluoromethanes from, 736, 737
—, crystalline forms of, 730
—, decarbonizing with, 731
—, decomposition of, 730
—, dehydration agent for alcohols, 407
—, dewaxing agent for oils, 731
—, dichlorodifluoromethane from, 733, 734
—, effect on decomposition of acetone, 450
—, — esterification of isopropyl alcohol, 376
—, — inflammability limits, 985, 986
—, — pentene-1-hydrogen bromide, reaction, 317
—, electrolysis of, 807
—, estimation of, 729, 731
—, extraction agent for asphaltenes, 1190
—, — naphthenic acids, 1108
—, — polymerized hydrocarbons, 397
—, — trinitrotoluene, 496
—, from carbon disulphide, 730
—, from chlorinated coal, 730
—, from chloromethane, 727
—, from methane, 726
—, from monofluorotrichloromethane, 737
—, from sulphur dichloride and carbon, 730
—, hexachloroethane from, 731
—, inflammability limits of, 980
—, phosgene from, 732, 733
—, phthalyl chloride from, 731, 732
—, precipitant for carbenes, 1193
—, properties of, 730
—, reaction with antimony trifluoride, 733, 734, 736
—, — calcium fluoride, 736, 737
—, — ethers, 345
—, — formaldehyde, 731
—, — petrolatum, 732
—, — phthalic anhydride, 731, 732
—, — sulphur, 469
—, refining agent for oils, 731
—, resin from, 217, 732
—, stabilization of, 733
—, tetrachloroethane from, 731
—, toxicity of, 733
—, trichlorofluoromethane from, 734
—, uses of, 545, 731, 732, 733, 746, 790
Carbonyl compounds, from polyhydric alcohols, 548
Carbonyl fluoride from fluoroform, 737
Carbonyls, as antioxidants for gasoline, 914
—, catalysts, oxidation of paraffin wax, 971
Carboxide, definition of, 556
Carboxylic acids, as extraction agents, 1060
—, catalyst, esterification of olefins, 314, 315
—, extraction with ethers, 418
—, from aldehydes, 885
—, from crude oil, 10
—, from kerosene, 860
—, from ketones, 432, 450
—, from naphthenes, 10
—, from nitrolic acids, 1094

Carboxylic acids, from olefins, 446
—, from paraffin wax, 856
—, from sapropels, 975
—, reaction with vinylacetylene, 706
—, as antioxidant for gasoline, 914
β-*o*-Carboxyphenyl-propionic acid, preparation of, 905
Carburol process, for cracking, 130
Carbyl sulphate, acetic acid from, 1081
—, from ethylene, 321, 1081, 1082
—, isethionic acid from, 1081
Carnauba wax, in polishing compositions, 1079
Caro's acid, hydroxylation of olefins, 532
Casein, in asphalt emulsion, 1219
—, in coating compounds, 1079
—, in insecticides, 1077
—, in synthetic plastics, 890
—, reaction with olefin oxides, 561, 562
Castor oil, as solvent, 1113
—, effect on ignition temperature, 998
—, extraction agent for resins, 1188
—, in brake fluid mixtures, 539, 542, 546
—, in insecticides, 1077
—, oxidized, in demulsifying agents, 1075
—, reaction with naphthenic acids, 1113
—, — resins, 217
—, solubility in di-*n*-propyl ketone, 443
—, — mineral oil, 759
—, sulphonated, in emulsifying agents, 1074
Catalysis, mechanism of, 633, 634
Catalysts, effect, on free energy change, 1296
Catechol, antioxidant for gasoline, 913, 917
—, effect on color stability, 926
Cathode rays, action on gaseous hydrocarbons, 267
Celite earth, catalyst, oxidation of toluene, 949
Celluloid, solvent for, 896
Cellulose, acetylation of, 496
—, etherification of, 559
—, petroleum from, 19
—, reaction with chlorohydrins, 559
—, — ethylene oxide, 558, 559
—, — olefins, 629
Cellulose acetate, plasticizer for, 498
—, solvents for, 415, 434, 443, 453, 582
Cellulose esters, in paints, 1115
—, plasticizers for, 582, 1120
—, reaction with butene oxide, 589
Cellulose ethers, plasticizers for, 1120
Cellulose films, preparation of, 728
Cellulose hydroxypropyl phthalate, preparation of, 588
Cellulose phthalate, reaction with propene oxide, 588
Cellulosic materials, oils from, 21
Cements, formaldehyde in, 890, 891
Ceramics, preparation of, 1057
Ceresin, acids from, 975
—, composition of, 16, 39
—, cracking of, 195
—, definition of, 1245
—, extraction agents for, 1245
—, from crude oils, 13
—, in dielectrics, 1255
—, oxidation of, 975
—, properties of, 39
—, sulphonation of, 39
—, voltolization of, 262
Ceria, catalyst, esterification of alcohols, 338
—, —, pyrolysis of ethylbenzene, 159
Ceric ions, catalysts, nitration of toluene, 954
Cerium, catalyst, chlorination of benzene, 778
—, —, oxidation of ethylene, 553
—, promoter, oxidation of methyl alcohol, 878, 879
—, —, reduction of carbon monoxide, 1229, 1232, 1236, 1240
Cerium acetylacetonates, catalysts, phenylcyclopentane autoxidation, 907
Cerium chloride, promoter, chlorination of methane, 726
Cerium nitrate, catalyst, methane-steam reaction, 278
Cerium oxide, catalyst, hydration of acetylene, 714
—, —, ketones from acids, 446
—, —, oxidation of aromatics, 942
—, —, — hydrocarbons, 850, 851, 871
—, —, reaction of methane and steam, 279
—, —, — nitric oxide and paraffins, 1091
—, promoter, dehydrogenation of isopropyl alcohol, 420
—, —, ethanol-steam reaction, 422
Cerium phosphate, catalyst, dehydration of 1,3-butene glycol, 174
—, —, reaction of ethers and alkylhalides, 345
Cerium sulphate, catalyst, oxidation of anthracene, 954
—, —, — hydrocarbons, 854
Cetane number, definition of, 1034
Cetene, reference standard, in Diesel fuel, 1033, 1034
Cetene number, definition of, 1034
Cetyl acetate, from cetyl alcohol, 438
Cetyl alcohol, acetylation of, 438
—, reaction with olefin oxides, 587, 588
Cetyl halides, glycol ethers from, 543
Chain reactions, in pyrolysis of hydrocarbons, 189
Chamotte, effect on pyrolysis of hydrocarbons, 189
Chancel degrees, definition of, 245
Channel process, for carbon black, 237
Characterization factor, critical temperature from, 1313
—, definition of, 1307
—, determination from aniline point, 1309
—, — hydrogen content, 1309
—, — molal average boiling point, 1307, 1309, 1310
—, — specific gravity, 1307, 1309, 1310
—, — viscosity index, 1309, 1310
—, heat of vaporization from, 1327
—, molecular weight from, 1311
—, of aromatics, 1307
—, of cracked gasoline, 1308
—, of crudes, 1308
—, of paraffins, 1307
—, of residuums, 1308
—, pseudocritical pressure from, 1318, 1319
—, pseudocritical temperature from, 1318, 1319
—, specific heat from, 1323, 1325
Charcoal, adsorption of gaseous hydrocarbons, 164, 1139
—, adsorption of helium, 1125, 1126
—, adsorption of hydrogen sulphide, 461
—, adsorption of liquid hydrocarbons, 23
—, adsorption of mazout, 1188
—, adsorption of resins, 1188
—, catalyst, chlorination of toluene, 793
—, —, dehydrogenation of thiophane, 484
—, —, isomerization of propene oxide, 586
—, —, oxidation of petroleum, 966
—, —, — sodium sulphide, 465
—, —, polymerization of diolefins, 667
—, —, — olefins, 666
—, —, reaction of methane and ammonia, 281
—, —, — methane and carbon oxides, 1049
—, desorption of olefins from, 164
—, in refining isopropyl alcohol, 365
Charging stock, effect on cracking, 107, 108
China wood oil, cracking of, 136
Chloral, from carbon tetrachloride, 731
Chloral deuterate, deuterio-chloroform from, 729
—, reaction with sodium deutroxide, 729
Chlorene, from acetylene, 89, 703
Chlorex, composition of, 43
Chlorex process, refining of oils, 43, 529, 530
Chloric acid, oxidizing agent for mercaptans, 480
ter-Chlorides, hydrolysis of, 413
Chlorinated biphenyls, from monochlorobenzene, 780, 781
Chlorinated hydrocarbons, effect of zinc on, 782
Chlorinated Kogasin, action of aluminum chloride on, 1253, 1254
—, reaction with aromatics, 1253, 1254
Chlorinated naphtha, resins from, 217

Chlorinated paraffins, effect on castor oil solubility, 759
—, in coating compositions, 759
—, in emulsifying agents, 822
—, lubricating oil from, 813
—, olefins from, 807
Chlorinated paraffin wax, lubricants from, 758, 817
—, reaction with benzene, 758
Chlorinated pentane, utilization of, 755
Chlorinated propane, resins from, 217
Chlorinated rubber, in coating compositions, 543
Chlorination, acetone, 430
—, acetylene, 709
—, benzene, 777-781
—, butadiene, 685
—, butane, 751, 752
—, butenes, 172, 508
—, *ter*-butyl alcohol, 627
— *n*-butyl chloride, 678
—, carbon disulphide, 730
—, carbon tetrachloride, 734
—, chloromethane, 727
—, cinnamic acid, 627
—, coal, products from, 730
—, cyclohexane, 765-767
—, cyclohexene, 767
—, cyclopropane, 760, 761
—, of deuterioacetylene, 742, 743
—, dichlorobenzenes, 781
—, difluoromethane, 734, 735
—, dimethyl ether, 529
—, 1,4-dithiocyanobutene, 698
—, divinylacetylene, 709
—, ethane, 741
—, ethyl alcohol, 626, 627
—, ethylene, 492
—, ethylene dichloride, 501, 742
—, formaldehyde, 887
—, gasoline, 755
—, hexane, 756
—, isobutane, 752
—, isobutene, 508
—, isopentadecane, 1253
—, isoprene, 686
—, Kogasin, 1253
—, Kogasin II, 815
—, menthane, 776
—, methane, 726-730
—, methyl alcohol, 626
—, monochlorobenzene, 780, 781
—, naphthenic alcohols, 1120
—, neopentane, 754
—, octane, 756
—, paraffins, rules for, 740
—, paraffin wax, 757
—, pentane, 753, 754
—, pentenes, 511, 512
—, petroleum-coal distillate, 781
—, petroleum distillates, 814
—, polychlorobenzene, 780, 781
—, polyprene, 682
—, propane, 749, 750
—, pyrene, 956
—, still gases, 741
—, tar, 756
—, toluene, 793, 794
—, trimethylcyclohexane, 775, 776
—, trimethylethylene, 513
—, of vinyl chloride, 716
Chlorine, action on hydrogen sulphide, 460
—, catalyst, oxidation of asphalts, 1205
—, —, pyrolysis of paraffins, 158, 168
Chlorine monoxide, chlorination of benzene, 781
Chloroacetaldehyde, from methylene chloride, 728
Chloroacetic acid, catalyst, ethylene oxidation, 894
—, from tetrachloroethane, 746
—, reaction with isopropyl alcohol, 376
—, — propene, 308
4-Chloroacetophenone, from chlorobenzene, 789
β-Chloroacid chlorides, reaction with alcohols, 611
1-Chloro-2-alkoxy-2-phenylpropionic acid, from cinnamic acid, 627
Chloroamine, reaction with ketene, 440
6-Chloro-8-amino-quinoline, reaction with N-aminodiethylethanol, 569
Chloroaniline, as refining agent, 46
Chlorobenzene, *p*-aminobiphenyl from, 787
—, aniline from, 786, 787
—, chlorinated biphenyl from, 780, 781
—, chlorination of, 780, 781
—, 4-chloroacetophenone from, 789
—, *p*-chlorobenzylbenzoic acid from, 789
—, dewaxing agent, 434
—, diphenylamine from, 787
—, diphenyl ether from, 788, 789
—, extraction of ethyl alcohol with, 327
—, from benzene 778, 780, 950
—, hydrolysis of, 782-784
—, in dyes, 782
—, oxidation of, 944
—, phenol from, 782-784
—, phenylphenol from, 785
—, reaction with acetic anhydride, 789
—, — ammonia, 786, 787
—, — benzoic acid, 805
—, — phthalide, 789
—, — potassium amide, 787, 810
—, — sodium sulphide, 785
—, triphenylamine from, 787
Chlorobenzenes, utilization of, 782
o-Chlorobenzoic acid, preparation of, 452
p-Chlorobenzylbenzoic acid, from chlorobenzene, 789
o-Chlorobenzylidene aminophenol, as antioxidant, 916
1-Chlorobutadiene, from 1,4-dichloro-2-butene, 685
—, properties of, 685
2-Chlorobutadiene, preparation of, 680
—, from chlorocyclohexene, 172
—, *see also* Chloroprene
1-Chlorobutane, *see* *n*-Butyl chloride
Chlorobutanes, dechlorination of, 806
—, from butane, 752, 1101
—, reaction with cellulose, 753
—, utilization of, 753
Chlorobutenes, from 2,2-dichlorobutane, 452
1-Chloro-2-butanol, 1-butene oxide from, 589
3-Chloro-2-butanol, ether, from 2-butene, 627
Chlorocarbonic esters, reaction with hydroxyalkylamines, 569
β-Chloro-β′-chloroisopropyl ether, preparation of, 529
Chlorocosane, definition of, 757
Chlorocresols, from chlorotoluenes, 794
2-Chlorocycloheptanol, from cycloheptene, 521
Chlorocyclohexane, from cyclohexene, 204
—, reaction with alkali, 767
—, — amines, 768
—, — cycloparaffins, 767
—, — sodium salts, 768
—, use in Grignard reaction, 767
—, utilization of, 758
Chlorocyclohexanol, preparation of, 767, 768
2-Chlorocyclohexanol, cyclohexane-1,2-diol from, 521
—, from cyclohexene, 520, 521
Chlorocyclohexene, chlorobutadiene from, 172
—, ethylene from, 172
2-Chlorocyclooctanol, preparation of, 521
Chlorocyclopentane, chlorination of, 763
—, preparation of, 763
—, pyrolysis of, 764
2-Chlorocyclopentanol, cyclopentane-1,2-diol from, 520
—, from cyclopentene, 520
Chlorodifluoromethane, from dichlorofluoromethane, 737
2-Chloro-1,2-dimethylcyclohexane, preparation of, 775
4-Chloro-1,3-dimethylcyclohexane, preparation of, 775
Chlorodimethyl ether, ethylene oxide from, 551
Chloroethanes, reaction with sulphuric acid, 829
Chloroethers, reaction with cyclohexadiene, 693, 694
—, — olefins, 613
—, — vinylacetylene, 707
β-Chloroethyl acetate, ethylene oxide from, 550
Chloroethylamines, preparation of, 570
α-Chloroethylbenzene, from styrene, 311

β-Chloroethyl-β′-chloroisopropyl ether, preparation of, 529
β-Chloroethyl chlorosulphinate, preparation of, 525
Chloroethyl methyl ketone, formation of, 611
—, lactic acid from, 451
2-Chloro-2-ethylpropane, preparation of, 513
β-Chloroethyl sulphite, preparation of, 525
Chlorofluoromethanes, from carbon tetrachloride, 736, 737
—, utilization of, 737-739
Chloroform, as dielectric, 728
—, as extraction agent, 728, 729, 1188, 1190, 1245
—, as solvent, 728
—, catalyst, in cracking, 114
—, chloropicrin from, 729
—, difluoromonochloromethane from, 737
—, estimation of, 729
—, from acetone, 430
—, from carbon tetrachloride, 807
—, from chloromethane, 727
—, in anesthetics, 728
—, in cleaning agents, 545
—, methyl chloride from, 729
—, monofluorodichloromethane from, 737
—, nitration of, 729
—, physiological effects, 1261, 1262
—, reaction with calcium fluoride and silver fluoride, 737
—, — *p*-dichlorobenzene, 729
—, — dichloroethylene, 811
—, — ethers, 345, 729
—, structure of, 728, 729
—, tri-(2,5-dichlorophenyl) methane from, 729
—, use in alcohol distillation, 327
2-Chlorohexolactone, from hex-3-enoic acid, 627
Chlorohydrin, from cycloheptene, 521
—, from glycerol, 516
Chlorohydrins, from olefinic acids, 627
—, olefin oxides from, 550
Chlorohydroquinone, as antioxidant, 916
Chloroisoamylene, reaction with hypochlorous acid, 523
Chloroisobutene, reaction with hypochlorous acid, 522
Chloroisoprene, preparation of, 721
Chloroketones, preparation of, 612, 613
Chloromethane, *see* Methyl chloride
1-Chloro-2-methoxy-2-phenylpropionic acid, from cinnamic acid, 627
Chloromethyl acetate, reaction with ethylene, 613
3-Chloro-2-methylallyl alcohol, preparation of, 797, 798
2-Chloro-2-methylbutane, *see ter*-Amyl chloride
2-Chloro-1-methylcyclohexanol, preparation of, 521
2-Chloro-1-methylcyclopentanol, preparation of, 521
α-Chloromethyl ether, reaction with olefins, 613
2-Chloro-2-methylpropane, *see ter*-Butyl chloride
1-Chloro-2-methyl-1-propene, preparation of, 509
1-Chloro-2-methyl-2-propene, preparation of, 509
Chloronaphthalenes, as solvents, 727
1-Chloro-4-naphthalenesulphonic acid, dehydration agent for di-*ter*-butylcarbinol, 401
1-Chloro-2-pentanol, 1-pentene oxide from, 589
3-Chloro-2-pentene, preparation of, 511, 513
p-Chlorophenol, from *p*-dichlorobenzene, 783, 784
—, phenol from, 784
Chlorophyll porphyrins, in petroleum, 12, 17
Chloropicrin, from chloroform, 729
—, from nitromethane, 1096
Chloroprene, co-polymerization of, 681, 682
—, formation of, 706
—, in synthetic rubber, 706
—, properties of, 681
Chloroprene, *see also* 2-Chlorobutadiene
Chloropropanes, chlorination of, 750
1-Chloro-1-propene, from propene dichloride, 508
Chloropropionic acid, lactic acid from, 451
—, preparation of, 451
2-Chloropropionyl chloride, preparation of, 609
Chlorostyrene, from methyl (chlorophenyl) chloromethane, 828
Chlorosulphonic acid, in wetting agents, 417, 1076
—, reaction with asphaltenes, 1191
—, — ceresins, 39
—, — lauryl diethylene glycol, 545
—, — naphthenic acids and aromatics, 1118
—, — olefins, 609
—, — paraffins, 32, 1102
Chloro-*n*-tetradecane, reaction with xylene, 1254
Chlorotoluene, bromination of, 795
—, from toluene, 793
—, hydrolysis of, 794
N-Chlorourea, reaction with cycloheptene, 521
—, — ethylene, 515, 516
Chromates, estimation with isopropyl alcohol, 375
Chrome alum, catalyst, ether from ethyl alcohol, 331
Chromel, catalyst, oxidation of paraffins, 874
—, —, pyrolysis of olefins, 77
Chromic acid, effect on gum formation, 924
—, catalyst, reaction of ethyl alcohol and carbon monoxide, 1041
—, —, — methyl alcohol and carbon monoxide, 1050
—, reaction with crudes, 1047
—, — isopropyl alcohol, 370
Chromic chloride, catalyst, pyrolysis of ethyl alcohol, 348
Chromic ions, catalysts, nitration of toluene, 954
Chromic oxide, catalyst, higher alcohols from ethanol, 339
—, —, oxidation of butyl alcohol, 880
—, —, pyrolysis of 2-butene, 172
—, —, — ethyl alcohol, 351, 421
—, —, — paraffins, 54, 73, 149, 1298
—, —, reduction of carbon monoxide, 1251, 1252
Chromite ore, sweetening agent, 479
Chromium, catalyst, oxidation of ethane, 872
—, —, — ethyl alcohol, 872
—, —, — methane, 869
—, —, — paraffin wax, 971
—, —, polymerization of olefins, 665
—, —, pyrolysis of alcohol, 348, 350
—, —, — hydrocarbons, 160, 185, 189
—, —, reaction of carbon disulphide and chlorine, 730
—, in cracking, 114
—, inhibitor, decomposition of ethylene oxide, 554
—, promoter, chlorination of benzene, 779
—, —, dehydrogenation of ethyl alcohol, 878
—, —, higher alcohols from ethanol, 340
—, —, oxidation of methyl alcohol, 878, 879
—, —, reduction of carbon monoxide, 1228
Chromium alloys, in cracking, 112, 134
—, in pyrolysis of hydrocarbons, 189
Chromium borate, in pyrolysis of paraffins, 160
Chromium carbonate, catalyst, oxidation of methane, 881
Chromium chloride, catalyst, decarboxylation of phthalic anhydride, 952
Chromium compounds, catalysts, hydrogenation of acetylene, 171
Chromium halides catalysts, hydration of acetylene, 712
Chromium hydroxide, catalyst, reaction of methane and steam, 278
—, —, — sulphur and hydrocarbons, 467
Chromium-lead ore, sweetening agent, 479
Chromium-nickel alloy, catalyst, polymerization of ketene, 441
—, in pyrolysis of hydrocarbons, 189
Chromium oxide, catalyst, dehydration of alcohols, 331, 420
—, —, hydration of acetylene, 714
—, —, oxidation of aromatics, 942, 945
—, —, — ethyl alcohol, 423
—, —, — hydrogen sulphide, 460
—, —, — methane, 871, 881
—, —, — *d*-*α*-pinene, 905
—, —, pyrolysis of hydrocarbons, 92, 159, 189, 227, 228
—, —, reaction of ethyl alcohol and steam, 422
—, —, — methane and steam, 278, 279
—, —, — sulphur and hydrocarbons, 467
—, —, reduction of carbon monoxide, 661, 1228
—, effect on ignition temperature, 1000

Chromium phosphate, catalyst, hydration of ethylene, *287*
Chromium salts, catalysts, acids from alcohols, 1051
—, —, reaction of olefins and carbon monoxide, 626
Chromium-silicon alloy, catalyst, acetylene pyrolysis, 89
Chromium sulphate, catalyst, ether from ethyl alcohol, 331
—, promoter, hydration of ethylene, 283
Chromous salts, catalysts, hydrogenation of acetylene, 719
Chrysene, from cracking gas, 646
—, from hydrindene, 95
—, from indene, 95
—, from natural gas, 183
—, from petroleum coke, 145
Cinnamaldehyde, cinnamyl alcohol from, 372
—, reaction with ketene, 439
—, — nitric acid, 851, 852
Cinnamates, catalysts, oxidation of paraffin wax, 971
Cinnamic acid, 1-chloro-2-methoxy-2-phenylpropionic acid from, 627
—, phenylglyceric acid from, 547, 895
—, reaction with *ter*-butyl alcohol and chlorine, 627
—, — ethyl alcohol and chlorine, 627
Cinnamyl alcohol, from cinnamaldehyde, 372
Cinnamylideneaminophenol, antioxidant, 916
Citric acid, antigelating agent, 330
—, decolorizing agent, 958
—, effect on paints, 576
—, reaction with phosphorus trisulphide, 484
Citronellal, *see* Citronell aldehyde
Citronell alcohol, blending agent for motor fuel, 1035
—, from citronell aldehyde, 372
Citronell aldehyde, citronell alcohol from, 372
Citronellol, *see* Citronell alcohol
Clark process, for cracking, 125
Clay, catalyst, alkylation of phenols, 603
—, —, chlorination of benzene, 778
—, —, hydrolysis of chlorobenzene, 782
—, —, in cracking, 112, 128
—, —, ozonization of gasoline, 1045
—, —, polymerization of olefins, 636, 666
—, —, pyrolysis of ethyl alcohol, 155
—, —, reaction of ethylene oxide and hydrogen sulphide, 564
—, decolorizing agent, 976, 977
—, desulphurizing agent, 1044
—, stabilizing agent for asphalt emulsions, 1219
—, use in refining gasoline, 134, 135, 669, 927, 928
Cleaning agents, acetic acid in, 1084
—, alcohols in, 1084
—, alkali salts in, 1112
—, carbon tetrachloride in, 731, 732, 746
—, *o*-dichlorobenzene in, 790
—, ethylene dichloride in, 745
—, ethylene glycol ethers in, 543
—, gasoline in, 746
—, glycerol in, 1112
—, hydroxyethyl ethers in, 558
—, kerosene in, 790
—, mahogany sodium sulphonate in, 746
—, methylene chloride in, 728
—, naphtha in, 746
—, naphthenic acids in, 1112
—, oleic acid in, 746
—, phosphoric acid in, 543
—, potassium sulphate in, 1112
—, red oil in, 790
—, saponin in, 543
—, sulpho detergents in, 1084
—, sulphonaphthenic acids in, 1118
—, tetrachloroethane in, 746
—, trichloropropane in, 751
Cloud point, definition of, 1176
Coagulating agent, ammonium naphthenate as, 1116
Coal, carbon from, 227
—, carbon monoxide from, 1246
—, catalyst, in cracking, 111
—, chlorination of, 227, 730
—, gasification of, 1246
—, hydrogenation of, 9
—, hydrogen from, 1246
—, lubricating oil from, 213
—, spraying with petrolatum, 41
Coal gas, as motor fuel, 27
—, ethylene from, 327, 328
—, ignition of, 1002
Coal tar, antioxidant for gasoline, 914
—, cracking of, 135
—, ethylation of, 210
Coal-tar distillates, reaction with ethylene, 593
Coal-tar oils, reaction with ethylene, 209
Coal-tar pitch, coking of, 230
Coating compositions, chlorinated paraffins in, 759
—, ethylene glycol ethers in, 543
—, formaldehyde in, 890, 891
—, from abietates, 543
—, from asphalt oil, 467
—, from casein, 1079
—, from chlorinated rubber, 543
—, from mahogany sulphonates, 1079
Cobalt, catalyst, hydration of ethylene, 291
—, —, oxidation of aromatics, 942
—, —, — ethylene, 553
—, —, — paraffin wax, 971
—, —, polymerization of pinene, 645
—, —, pyrolysis of olefins, 76
—, —, — paraffins, 158, 189
—, —, — pinene, 88
—, —, reaction of allyl bromide and hydrogen bromide, 316
—, —, — carbon and hydrogen, 1278
—, —, — methane and steam, 270, 279
—, —, reduction of carbon monoxide, 1223-1225, 1228-1230, 1232, 1233, 1236, 1237, 1240, 1242, 1244, 1249, 1250
—, effect on pyrolysis of benzene, 191
—, electrodeposition of, 571
—, promoter, chlorination of benzene, 779
—, —, in cracking, 114, 128, 129
—, —, reduction of carbon dioxide, 1242
Cobalt acetate, catalyst, oxidation of acetone, 432
—, in drying agents, 1055
—, promoter, oxidation of acetaldehyde, 885
Cobalt acetylacetonate, catalyst, phenylcyclopentane autoxidation, 907
Cobalt amines, as antiknocks, 1018
Cobalt antimonide, catalyst, dehydrogenation of alcohols, 419
Cobalt arsenide, catalyst, dehydrogenation of alcohols, 419
Cobalt bismuthate, catalyst, dehydrogenation of alcohols, 419
Cobalt boro-phosphate, catalyst, hydration of propene, 292
Cobalt bromide, detection, moisture in oil, 28
Cobalt carbonate, catalyst, methane-steam reaction, 278
—, —, oxidation of methane, 881
Cobalt chloride, reaction with ethanolamines, 570
—, — tripropanolamine, 587
Cobalt compounds, catalysts, oxidation of *d*-α-pinene, 905
—, —, sulphation of ethylene, 323
Cobalt cyanide, catalyst, sulphation of olefins, 358, 391
Cobalt fluoride, catalyst, reaction of propene and hydrogen fluoride, 307
Cobalt halides, catalysts, pyrolysis of paraffins, 158
—, —, reaction of dichloroethane and hydrogen fluoride, 747
—, —, — olefins and carbon monoxide, 625
Cobalt hydroxide, catalyst, reaction of methane and steam, 278
—, —, — sulphur and hydrocarbons, 467
Cobalt iodide, reaction with triethanolamine, 571
Cobalt naphthenate, antioxidant for lubricants, 937
—, as drying agent, 1115
—, in purification of naphthenic acids, 1105

Cobalt nitrate, catalyst, methane-steam reaction, 278
—, in cracking, 112
Cobalt nitrosocarbonyl, as antiknock, 1018
Cobalt oleate, catalysts, oxidation of *d*-α-pinene, 905
Cobalt oxide, catalyst, oxidation of aromatics, 942
—, —, — methane, 866, 881
—, —, pyrolysis of benzene, 192
—, —, pyrolysis of thiophene, 483
—, —, reaction of steam and acetylene, 714
—, —, — steam and ethanol, 422
—, —, — steam and methane, 278
—, —, — sulphur and hydrocarbons, 467
—, effect on ignition temperature, 1000
—, for removal of sulphur compounds, 397
—, promoter, in cracking, 114, 129
Cobalt phosphate, catalyst, hydration of ethylene, 284
—, —, — propene, 292
Cobalt phosphide, catalyst, dehydrogenation of alcohols, 419
Cobalt salts, catalysts, acids from alcohols, 1051
—, —, sulphation of isoolefins, 308
—, —, sulphation of propene, 358
—, reaction with triethanolamine, 572
Cobalt selenide, catalyst, dehydrogenation of alcohols, 419
Cobalt soap, catalyst, oxidation of oils, 1044
Cobalt sulphate, promoter, hydration of ethylene, 283
Cobalt sulphide, catalyst, hydration of acetylene, 712
—, —, pyrolysis of benzene, 191
Cobalt telluride, catalyst, dehydrogenation of alcohols, 419
Coconut oils, sulphates from, 1084
Coffee, decaffeination of, 710
Coke, analysis of, 145
—, as fuel, 231, 232
—, carbon from, 230-232
—, carbon black from, 222
—, carbon monoxide from, 1247
—, catalyst, in cracking, 111
—, —, pyrolysis of acetylene, 89
—, —, — paraffins, 71, 158
—, —, reaction of steam and coke-oven gas, 1247, 1248
—, —, — steam and hydrocarbons, 272, 276
—, —, reduction of carbon dioxide, 1241
—, —, reduction of carbon monoxide, 1241
—, from aromatics, 109
—, from coal tars, 135, 230
—, from crudes, 140
—, from gas oil, 102, 110
—, from lubricants, 930, 931
—, from petroleum distillates, 197
—, from petroleum residues, 229-232
—, from resins, 1189
—, hydrocarbons in, 145
—, hydrogen from, 1247
—, reaction with carbon dioxide, 1247
—, — steam, 1247
Coke-oven gas, acetylene from, 170
—, adsorption with copper oxide, 552
—, benzene from, 165
—, butene from, 165
—, carbon monoxide from, 1246-1248
—, cyclopentadiene from, 679
—, ethylene oxide from, 552
—, extraction with butanolamine, 590
—, hydrogen from, 1246-1248
—, hydrogen sulphide from, 165
—, propene from, 165
—, reaction with steam, 1247, 1248
Colloidal systems, of asphalts, 1195-1198
Color stability, effect of sulphur compounds on, 454-456
—, tests for, 925
Color stabilizers, for gasoline, 926, 927
Columbium oxide, catalyst, oxidation of aromatics, 942
Columbium pentachloride, catalyst, alkylation of aromatics, 596
Combustion, effect of carbon dioxide, 1004
—, — nitrogen, 1004
—, estimation of hydrocarbons, 1128-1132
—, — sulphur, 1127, 1162, 1163
—, flame propagation in, 1005, 1006
—, increase of pressure during, 1002-1005
—, mechanism of, 1012-1016
—, of acetylene, 1001, 1003, 1004
—, of alcohols, 999, 1004, 1005
—, of aromatics, 999, 1003-1005
—, of carbon black, 245
—, of carbon disulphide, 1003, 1004
—, of carbon monoxide, 1010
—, of fuels, mechanism, 1012, 1013
—, of hydrogen, 1003, 1004
—, of olefins, 1001, 1003-1005, 1010
—, of paraffins, 999, 1000, 1003-1005, 1011, 1012, 1014, 1015
—, of phenols, 999
—, submerged, 1061
Compression, use in ignition, 1000, 1001
Concatenation, definition of, 632
Condensation, fractional, estimation of gaseous hydrocarbons, 1132, 1133
—, aldehydes, 886, 889
Coniferous wood, resins from, 46
—, terpenes from, 46
Contact time, effect on pyrolysis of paraffins, 56, 57, 150-152, 166, 188
Co-polymerization, of 1-chlorobutadiene, 685
—, of chloroprene, 681, 682
—, of monovinylacetylene, 685
Copper, catalyst, acetone from acetaldehyde, 423
—, —, chlorination of benzene, 778, 779
—, —, cyclic ethers from dialkyl haloethers, 551
—, —, decomposition of carbon tetrachloride, 730
—, —, dehydrogenation of alcohols, 337, 340, 419, 420, 443, 878, 1051

—, —, — ketones and alcohols, 443
—, —, — methyl chloride and carbon monoxide, 727
—, —, — methylene iodide and sodium sulphite, 819
—, —, — phthalic anhydride and carbon monoxide, 950
—, —, sulphation of polymerized hydrocarbons, 365
—, —, — propene, 358
—, effect on color stability, 925

Copper, effect on oxidation of transformer oil, 938, 939
—, — polymerization of butadiene, 651
—, in aging test for lubricants, 932
—, in refining gasoline, 668
—, inhibitor, decomposition of ethylene oxide, 554
—, —, oxidation of ether, 336, 337
—, promoter, hydration of ethylene, 283
—, —, in cracking, 114, 128
—, —, methane-carbon dioxide reaction, 274
—, —, oxidation of cracking gas, 881
—, —, reduction of carbon dioxide, 1242, 1247
—, —, — carbon monoxide, 1228-1232, 1236, 1237, 1240, 1241, 1249
Copper acetate, promoter, oxidation of acetaldehyde, 885
Copper acetylacetonate, catalyst, phenylcyclopentane autoxidation, 907
Copper alloys, catalysts, dehydration of alcohols, 419, 420
— in cracking, 134
Copper aluminum silicate, catalyst, reaction of phthalic anhydride and carbon monoxide, 950
Copper borate, catalyst, pyrolysis of paraffins, 160
Copper boro-phosphate, catalyst, hydration of ethylene, 285
—, —, — propene, 292
Copper bromide, catalyst, esterification of propene, 308
Copper carbonate, catalyst, decarboxylation of phthalic anhydride, 950
—, —, oxidation of petroleum, 966
—, promoter, reduction of carbon monoxide, 1231
Copper chloride, catalyst, alkylation of amines, 347
—, —, chlorination of propane, 750
—, —, esterification of propene, 308
—, desulphurizing agent, 488
—, refining agent for gasoline, 928
Copper chromate, catalyst, hydration of vinylacetylene, 705
Copper chromite, catalyst, butanol from ethanol, 341
—, —, dehydrogenation of alcohols, 420
—, —, hydrogenation of butyl lactate, 546
Copper compounds, catalyst, ethylene-sulphuric acid reaction, 323
—, effect on color stability, 938
Copper cyanide, catalyst, sulphation of isobutene, 391
Copper dish, estimation of gum formation, 910
Copper halides, catalysts, pyrolysis of paraffins, 158
—, —, reaction of dichloroethane and hydrogen fluoride, 747
—, —, — olefins and carbon monoxide, 625
Copper hydroxide, catalyst, oxidation of gasoline, 266
—, —, — petroleum, 966
Copper manganates, catalysts, hydration of vinylacetylene, 705
Copper mercaptides, formation of, 476, 477
Copper naphthenate, as antioxidant, 937
—, as preservatives, 1116
—, as wetting agent, 1117
—, catalyst, polymerization of butadiene, 651, 1116
—, in paints, 1115
—, in wood preservatives, 1115
Copper β-naphtholallylamine, as antiknock, 1018
Copper oleate, catalyst, oxidation of naphtha, 876
—, —, polymerization of butadiene, 651
Copper oxide, as sweetening agent, 667
—, catalyst, acetone from ethanol, 422, 423
—, —, alkylation of amines, 347
—, —, dioxane from β, β′-dichlorodiethyl ether, 579
—, —, dipropyl ketone from *n*-butanol, 443
—, —, esterification of alcohol, 337
—, —, ethylene oxide from ethylene chlorohydrin, 550
—, —, hydration of acetylene, 712
—, —, hydrogenation of sulphur compounds, 1248, 1249
—, —, hydrolysis of chlorobenzene, 782
—, —, methane-steam reaction, 278
—, —, oxidation of alcohols, 844, 879
—, —, — aromatics, 942
Copper oxide, catalyst, oxidation of ethane, 872
—, —, — hydrogen, 165, 190
—, —, — methane, 867, 869, 871
—, —, — olefins, 553
—, —, polymerization of ethylene, 637
—, —, pyrolysis of methane, 54
—, —, — natural gas, 227
—, desulphurizing agent, 489
—, effect on ignition temperature, 1000
—, promoter, in cracking, 112
—, —, oxidation of toluene, 950
—, —, reduction of carbon monoxide, 1231
—, refining naphthenic acids, 1109
Copper phosphate, catalyst, alcohol-carbon monoxide reaction, 339, 407
—, —, esterification of propene, 308
—, —, hydration of ethylene, 284, 291
—, —, — propene, 292
Copper protocatechualethylamine, as antiknock, 1018
Copper salicylalallylamine, as antiknock, 1018
Copper salicylalmethylamine, as antiknock, 1018
Copper salts, catalysts, acids from alcohols, 1051
—, —, ethylene oxide from ethylene chlorohydrin, 550
—, —, for sweetening, 476-478
—, —, hydration of vinylacetylene, 705
—, —, polymerization of olefins, 929
—, —, sulphation of isoolefins, 308
—, —, sulphation of propene, 358
—, extraction of olefins with, 163
—, promoters, oxidation of toluene, 950
—, —, polymerization of olefins, 634
Copper silicate, in refining gasoline, 669, 930
Copper soap, catalyst, oxidation of oils, 1044
Copper stearate, catalyst, oxidation of mineral oil, 856, 938, 939
Copper sulphate, catalyst, ether from ethyl alcohol, 331
—, —, esterification of propene, 308
—, —, ethylation of amines, 347
—, —, hydration of vinylacetylene, 705
—, —, lubricants from chlorinated paraffin, 828
—, —, oxidation of petroleum, 966
—, dehydration agent, 364
—, preparation of drying agents, 1055
—, reaction with triethanolamine, 571
Copper sulphide, catalyst, pyrolysis of benzene, 191
Copper-tin alloy, catalyst, pyrolysis of ethane, 149
Copper-uranium, catalyst, esterification of alcohol, 339
Copper vanadate, catalyst, hydration of vinylacetylene, 705
Corn, lecithin from, 728
Corn gluten, emulsifying agent, 1218
Corn oil, antioxidant for gasoline, 918
—, effect on color stability, 926
Corona discharge, action on aromatics, 260
Corrosion inhibitor, alkalies, 477
—, benzyl chloride, 794
—, copper compounds, 477
—, cyclohexene, 477
—, tetrahydronaphthalene, 477
—, zinc naphthenate, 1116, 1117
Cottonseed meal, pyrolysis of, 840
Cottonseed oil, cracking of, 136
Cracked distillates, cyclopentadiene from, 679
—, reaction with acetaldehyde, 625
—, — formaldehyde, 625
—, — α-naphthoquinone, 679
—, refining with sulphuric acid, 1075, 1076
—, sulphonic acids from, 1075, 1076
Cracked fuel, production of, 98
Cracked gasoline, butyric acid from, 854
—, characterization factor of, 1308
—, composition of, 1045
—, from Kogasin, 1252, 1253
—, glycols from, 854
—, gums from, 1054
—, oils from, 214

Cracked gasoline, reaction with ethylene, 1252, 1253
—, — furfuraldehyde, 625
—, — phenols, 604
—, resins from, 625
Cracked oils, olefins from, 161
Cracked tar, ethylene from, 155
—, voltolization of, 262
Cracking, commercial processes, 115-131
—, coke from, 109
—, effect of catalysts, 103
—, — pressure, 106, 107
—, — recycling, 109, 130
—, — temperature, 103, 104
—, effect on aromatics, 108
—, — naphthenes, 108
—, — octane number, 1033
—, — paraffins, 108
Cracking, electrical, 131
—, in distillation, 30
—, of amines, 158
—, of amylcyclohexane, 137
—, of bicyclohexyl, 137
—, of coal tars, 135
—, of crude oil, 140
—, of cyclohexane, 136
—, of decalin, 137
—, of ethylbenzene, 159
—, of gas oil, 139, 140
—, of gasoline, 136, 139
—, of kerosene, 137, 139
—, of Kogasin, 1252, 1253
—, of methane, 1017
—, of methylisopropylbicyclononane, 137
—, of naphtha, 139
—, of paraffin wax, 138
—, of propane-steam mixtures, 149
—, of sapropelite tar, 135
—, of *n*-tetradecane, free energy change, 1297
—, of wax acids, 979
—, thermodynamics of, 99-103
Cracking gas, butadiene from, 171
—, ethane from, 301
—, ethylene from, 301
—, methane from, 301
—, oxidation of, 881
—, production of, 654
—, reaction with benzene, 593, 594
—, — ethylene, 1252, 1253
—, — sulphuric acid, 359
—, removal of olefins from, 324
—, utilization of, 164, 631, 654
Cracking oil, detergents from, 1083
Cracking residuum, effect on pyrolysis of paraffins, 158
Creosote, extraction with isopropyl alcohol, 373
Creosote, lampblack from, 242
—, reduction of, 264
Cresol, antioxidant for gasoline, 914, 915
—, extraction agent for alcohols, 360, 391
—, from chlorotoluene, 794
—, in lubricating oils, 43
—, reaction with acetylene, 715
o-Cresol, from ethyl alcohol, 173
—, reaction with *ter*-butyl alcohol, 416
m-Cresol, antioxidant for transformer oil, 941
—, reaction with ammonia, 788
—, — *ter*-butyl alcohol, 412
—, *m*-toluidine from, 788
m-Cresol methyl ether, reaction with *ter*-butyl alcohol, 416
p-Cresol, stabilizing agent for methyl chloride, 727
Cresylic acid, extraction agent for olefins, 163
Critical compression ratio, definition of, 1024
—, relation to boiling point, 141
Critical oxidation potential, definition of, 920
Critical pressure, determination of, 1313-1318
Critical solution temperature, determination of, 1178, 1180
Critical temperature, determination of, 1311-1313
—, critical pressure from, 1314, 1315, 1318
Cross process, for cracking, 118
Crotonaldehyde, butanol from, 889
—, butyraldehyde from, 889
—, crotyl alcohol from, 372
Crotonaldehyde, extraction of lubricating oils with, 43
—, from acetaldehyde, 878, 889
—, hydrogenation of, 889
Crotonic acid, dihydroxybutyric acid from, 547
Crotyl alcohol, from crotonaldehyde, 372
Crotyl bromide, reaction with hypochlorous acid, 523
Crude oil, acids in, 10, 21
—, adamantane in, 35
—, albuminous substances in, 12
—, aquolysis of, 132
—, aromatics in, 13, 31, 32, 35, 1149
—, asphaltenes in, 13, 1189, 1190
—, asphaltogenic acids in, 1194, 1195
—, carbon dioxide in, 10
—, ceresin in, 13
—, characterization factors of, 1308
—, composition of, 10-12, 29, 46
—, cracking of, 97, 140
—, emulsifying agents from, 1217
—, emulsions in, 10
—, enthalpy-temperature relations, 1334, 1335
—, entropy-temperature relations, 1340, 1341
—, fractionation of, 21, 24, 28, 31, 34, 97, 116
—, inorganic constituents of, 46-48
—, naphthalene from, 179
—, naphthenes in, 10, 13, 31-34, 1149
—, naphthenic acids in, 10, 1103, 1104
—, nitrogen compounds in, 10, 17
—, nitrotoluene from, 35
—, optically active constituents in, 12, 17
—, origin of, 16-21
—, oxidation of, 938, 1190
—, oxygenated compounds in, 17
—, paraffins in 10, 13, 32, 33, 1149
—, phenols in, 10
—, porphyrins in, 12, 17
—, refining of, 28
—, resins from, 1189
—, specific heat determination, 1323
—, sulphur compounds in, 10-12, 17
—, water in, 10
—, vanadium in, 20, 46, 47
—, world consumption, 10
—, world production, 7
Crystal oil, viscosity of, 15
Cumarone, in gasoline, 144
Cumene, from benzene, 382, 383, 402
—, from pinene, 88
Cuprene, preparation of, 704
—, utilization of, 704
Cupric acetate, catalyst, esterification of alcohol, 338
Cupric chloride, catalyst, chlorination of benzene, 778
—, —, — ethane, 741
—, —, — methane, 726
—, —, — perchloroethylene, 742
—, —, —propane, 750
—, —, ethylene chlorohydrin from ethylene, 515, 516
—, —, pyrolysis of ethyl alcohol, 348, 351
—, —, reaction of acetylene and aniline, 719
—, —, reaction of 2-butene and chlorourea, 509
—, in preparation of fumigants, 566
—, reaction with mercaptans, 477
—, refining agent for oils, 1044
Cupric compounds, catalysts, oxidation of hydrocarbons, 1043
Cupric oxide, catalyst, oxidation of ethane, 1131
—, —, — hydrocarbons, 1049
—, —, — methane, 1128
—, —, — paraffin oils, 907, 931
—, —, reaction of alcohols and ketones, 443
—, —, — methyl chloride and formaldehyde, 727
Cupric phosphate, catalyst, hydrolysis of chlorobenzene, 783
Cuprous chloride, absorption of acetylene by, 1124
—, — carbon monoxide by, 1124, 1125
—, — diolefins by, 165, 175, 359, 391
—, catalyst, chlorination of vinylacetylene, 687
—, —, hydrolysis of chlorobenzene, 782, 783
—, —, polymerization of acetylene, 704, 705
—, —, reaction of acetylene and aniline

Cuprous chloride, catalyst, reaction of carbon monoxide and benzene, 957
—, —, — ethylene and sulphuric acid, 322, 323
—, —, — ethylene dichloride and ammonia, 497
—, —, — hydrogen chloride and acetylene, 716
—, —, — hydrogen chloride and isopropenylacetylene, 721
—, —, — hydrogen chloride and vinylacetylene, 680, 706
—, reaction with ethylene, 163
Cuprous cresolate, absorption of ethylene by, 164
Cuprous cyanide, catalyst, sulphation of ethylene, 323
—, —, — propene, 358
Cuprous formate, absorption of carbon monoxide by, 234
Cuprous lactate, absorption of carbon monoxide by, 234
Cuprous nitrate, absorption of ethylene by, 164
Cuprous oxide, catalyst, hydration of propene, 360
—, —, hydrolysis of chlorotoluene, 794
—, —, reaction of chlorobenzene and ammonia, 786
—, —, — ketones and alcohols, 443
—, —, — propene and phosphoric acid, 358
—, —, sulphation of ethylene, 323
—, inhibitor, decomposition of ethylene oxide, 554
—, —, peroxides in ether, 335
—, reaction with *p*-dichlorobenzene, 784
Cuprous phenolate, absorption of ethylene by, 164
Cuprous salicylate, absorption of ethylene by, 164
Cuprous salts, catalyst, polymerization of acetylene, 704
Cyanamide, as antiknock, 1018
Cyanic acid, as antiknock, 1018
Cyanides, reaction with alkyl halides, 822
Cyanoanilide, as antiknock, 1018
Cyanobutadiene, from cyclohexenenitrile, 172
Cyanogen, ignition temperature of, 987
Cyanohydrins, from aldehydes, 886
—, hydrolysis of, 886
Cyclic acetals, from polyhydric alcohols and acetylene, 715
—, — and aldehydes, 544
Cyclic alcohols, esterification of, 1118-1120
Cyclic sulphones, from diolefins, 176
Cyclobutane, halogenation of, 762, 763
1,3-Cyclobutanedione, from ketene, 441
Cyclobutanol reaction with hydrogen bromide, 762
Cyclobutanone, preparation of, 762
Cyclobutene, reaction with halogens, 762
Cyclobutylmethanol, reaction with hydrogen bromide, 764
Cycloheptane, dehydrogenation of, 94
Cycloheptene, reaction with N-chlorourea, 521
Cyclohexadiene, auto-ignition of, 1017
—, effect of lead tetraethyl on, 1022
—, from *n*-butene, 81
—, reaction with aryl halides, 693, 694
—, — bromoacetamide, 531
—, — chloroethers, 693, 694
—, — methyl hypobromite, 531
—, — triphenylchloromethane, 694
1,3-Cyclohexadiene, *see* Cyclohexadiene
Cyclohexadiene oxide, from cyclohexadiene dibromide, 589
—, reaction with perbenzoic acid, 589
—, — phosphorus pentabromide, 589
Cyclohexane, action of aluminum chloride on, 204, 206, 445
—, as anesthetic, 1266, 1267
—, bicyclohexyl from, 205
—, bromination of, 769, 770
—, catalyst, reaction of propene and hydrogen bromide, 306
—, chlorination of, 765-767
—, condensation of, 205
—, cracking of, 101, 111, 136
—, dehydrogenation of, 92, 101, 185, 204, 1041
—, effect of lead tetraethyl on, 1022
—, effect on peroxide formation, 923
—, — ethylation of, 205
—, — photochemical decomposition of acetone, 450
—, explosive characteristics of, 1011, 1017
—, extraction agent for polymerized hydrocarbons, 397
Cyclohexane, fluorination of, 773, 774
—, free energy of formation, 1225, 1226
—, —, effect of temperature on, 1295
—, from benzene, 1298
—, from *n*-butene, 81
—, from di-*n*-heptyl mercury, 71
—, from *n*-hexane, 198
—, from methylcyclohexane, 206
—, from methylcyclopentane, 89
—, from *n*-tetradecane, 1297

—, — isobutane, 602
Cyclopropene, from dibromocyclopropane, 762
—, isomerization of, 88
—, reaction with bromine, 761, 762
Cylinder oil, cracking of, 137
—, in detergents, 1073
—, oxidation of, 1043
Cymene, from pinene, 88
—, from toluene, 382, 401, 402
—, reaction with *ter*-butyl alcohol, 412, 416

D

De-alkylation, of aromatics, 37
Decaethylene glycol, preparation of, 544, 545
Decahydronaphthalene, decomposition of, 206
—, diluent, acetylene polymerization, 703
—, in motor fuel, 1039
Decalin, autoxidation of, 907
—, cracking of, 93, 137
—, reaction with aluminum chloride, 206
Decane, chlorinated, reaction with benzene, 758
—, from carbon monoxide and hydrogen, 1245
—, from petroleum, 32
Decarbonizing, by carbon tetrachloride, 731
—, by chlorobenzene, 782
—, by *o*-dichlorobenzene, 790
—, by oleic acid, 790
—, by triethanolamine, 790
Decene, in gasoline, 144
—, from chlorinated paraffins, 807
Dechlorination, of acetylene tetrachloride, 710
Decolorizing agents, for asphalts, 1192
—, preparation of, 486
Decolorizing, by clay, 976, 977
3-Decyn-1-ol, preparation of, 565
DeFlorez process, of cracking, 120
Dehalogenation, of chlorinated kerosene, 807
Dehydration, of ethyl alcohol, 328, 329, 330, 1051
—, of glycols, 548
—, of hydroxy-acids, 968
—, of isopropyl alcohol, 173
—, of tertiary alcohols, 394, 901
Dehydroacetic acid, from acetylketene, 442
Dehydrogenation, of acenaphthene, 955
—, of alcohols, 173, 337, 348, 878, 1051
—, of cyclohexene, 185, 186
—, of ethylbenzene, 156
—, of naphthenes, 31, 33, 89, 91, 92, 94, 141, 1041, 1149, 1150
—, of paraffins, 94, 99, 101, 107, 148, 149, 158
—, —, free energy change, 1284, 1298
—, of thiophane, 484
—, of 1,1,4-trimethylcycloheptene, 94
De-inking agents, sulphates as, 1086
Demethanation, of dicyclopentadiene, 156
Demethylation, in pyrolysis, 101

Demulsibility, of asphalt emulsions, 1221
Demulsifying agent, ammonium naphthenate as, 1116
—, black kontakt as, 1075
—, calcium chloride as, 1105
—, ethyl alcohol in, 1075
—, fatty acids in, 1075
—, gas oil as, 1107
—, kerosene in, 1075
—, lubricating oil in, 1115
—, naphthenic acids as, 1111, 1112, 1114
—, oxidized castor oil in, 1075
—, sodium chloride as, 1108, 1111, 1112
—, sodium hydroxide as, 1111, 1112
—, sulphates as, 1085, 1086
—, sulphonic acids as, 1074, 1075, 1116
Denaturants, from acid sludge, 486
—, by oxidation of distillates, 1053
Denigès' reagent, detection of isopropyl alcohol, 371
Denoxol, denaturant, 876
Denoxol-Solve, gum inhibitor, 876
Density determinations, in gas analysis, 1134, 1135
Depolymerization, of olefins, 101
Derris, in insecticides, 1078
Desoxo-phyllerythrin, in oil shale, 19
Desoxophyllerythroatioporphyrin, in oil shale, 19
Destructive distillation, theory of, 16
Desulphurization, of gases, 1044
Desulphurization, with ozone, 1044, 1045
Desulphurizing, with hydrogen, 670
Detektol O. Special, odorizer, 876
Detergents, ammonium sulphonate as, 1069
—, cylinder oil in, 1073
—, from cracking oil, 1083
—, from ethylene chlorohydrin, 526
—, from fatty acids, 1084
—, from mercaptans, 487
—, Igepons as, 1082
—, naphthenic acids in, 1112
—, oleyl ethylene diamine as, 809
—, spindle oil in, 1073
—, sulphate, sulphonates in, 1086
—, sulphates in, 1073, 1074, 1082-1086
—, sulphonaphthenic acids in, 1112
—, sulphonic acids in, 1069, 1073, 1074, 1082-1086
—, urea in, 1073
—, wax acids in, 978
Deurag, composition of, 26
Deuterioacetaldehyde, formation of, 725
Deuterioacetylene, polymerization of, 266, 725
—, synthesis of, 724, 725
Deuteriobenzene, preparation of, 273
Deuteriochloroform, preparation of, 729
Deuterium, in benzene, 206
—, inflammability limits of, 982, 983
Deuterium chloride, action on benzene, 207
Deuterium oxide, reaction with benzene, 260, 273
—, — calcium carbide, 743
—, — trichloroacetaldehyde, 729
Dewaxing, of lubricants, 744, 745, 1044
—, of residual oils by propane, 46
—, with butyl alcohol, 728
—, with carbon tetrachloride, 731
—, with chlorobenzenes, 782
—, with chlorofluoromethanes, 738, 739
—, with ethyl chloride, 738, 739
—, with methyl chloride, 738, 739
—, with methylene chloride, 728
—, with naphtha, 728
Diacetone alcohol, from acetone, 427, 430
—, from mesityl oxide, 430
—, motor fuel from, 1040
—, use as solvent, 427
Diacetylene, acetone solvent for, 170
—, butadiene from, 677, 678
—, from petroleum hydrocarbons, 255
2, 3-Dialkyldioxanes, preparation of, 581
Dialkyl oxalates, as antiknocks, 1017
Dialkyl phthalates, as antiknocks, 1017
Dialkyl sulphates, hydrolysis of, 325, 326, 327
—, preparation of, 392
Diallyl, pyrolysis of, 88
o-Diaminobenzene, from *o*-dichlorobenzene, 787
Diaminodiphenylamine, as antioxidant, 917
Diaminofluorenes, as antioxidants, 918
1,2-Diamino-2-methylpropane, *see* Isobutenediamine
Diaminophenols, as antioxidants, 916
Diamylamine, reaction with 1,10-dichlorodecane, 810
Diamyl ether, from ethyl alcohol, 337
sec-Diamyl sulphate, preparation of, 309
Diaryl arylenediamines, as antioxidants, 917
Diaryl ethers, from chlorobenzenes, 782
Diarylguanidines, as antioxidants, 915
Diaryl hydrocarbons, refining of, 193
Diaryl ketones, from chlorobenzenes, 782
Diaryl dioxanes, preparation of, 581
Diazines, from cottonseed meal, 840
Diazoaminobenzene, catalyst, polymerization of butadiene, 651, 673
Diazomethane, reaction with trichloroacetyl glycol, 540
Diazonium chlorides, reaction with olefins, 700
2,3,10,11-Dibenzoperylene, from phenanthrene, 208
Dibenzylperylenes, as antioxidants, 918
Dibenzoyl peroxide, catalyst, esterification of olefins, 318
Dibenzylamine, reaction with olefin oxides, 560, 589
β-Dibenzylaminoethyl alcohol, preparation of, 560
1-Dibenzylamino-2-methyl-2-propanol, preparation of, 589
Dibenzyl-amino-phenol, as antioxidant, 916
Dibiphenylene ethylene, reaction with amines, 615
—, — ammonia, 615
Dibromoallyls, preparation of, 315, 316
Dibromoamine, reaction with ketene, 440
Dibromobenzene, from benzene, 791
1,2-Dibromobutane, reaction with sodium amide, 829
1,4-Dibromobutane, from butadiene, 684, 685
1,4-Dibromobutene, preparation of, 683
Dibromocyclobutane, hydrolysis of, 762, 763
—, preparation of, 762
—, reaction with bromine, 763
Dibromocyclohexane, preparation of, 770
—, reaction with phthalimide, 772
—, — quinoline, 772
Dibromocyclopentane, preparation of, 764
Dibromocyclopropane, cyclopropene from, 762
—, hydrolysis of, 762
β,β′-Dibromodiethyl ether, reaction with aniline, 583
Dibromomethylcyclohexanes, preparation of, 775
1,2-Dibromopentane, dehalogenation of, 514
1,4-Dibromopentane, preparation of, 763
Dibromopropanes, preparation of, 315
Dibutadiene, antiknock properties of, 1027, 1028
Dibutanolamine, preparation of, 588
Di-β-butoxyethyl ethyleneglycol diphthalate, preparation of, 542
Di-*ter*-butylcarbinol, *see* 2,2,4,4-Tetramethylpentanol-3
Dibutylamine, catalyst, ethylene dichloride-sodium polysulphide reaction, 499
—, —, vinylacetylene-hydrogen sulphide reaction, 709
Dibutylbenzenes, preparation of, 208, 592, 594
2,3-Di-*ter*-butyl-1,3-butadiene, preparation of, 679
Dibutyl ether, preparation of, 337
—, pyrolysis of, 87
Di-*ter*-butylethylene, formation of, 411
Di-*n*-butyl ketone, from *n*-valeric acid, 446
Dibutylnaphthalenesulphonamide, reaction with ethylene oxide, 562
Dibutylnitrosoamine, use in fuels, 1098
2,4-Dibutyl-*ter*-butylphenol, preparation of, 418
Dibutyl phthalate, stabilizer for gasoline, 915
Dibutyl phthalate, use, as absorbent, 738
Dibutyl sulphate, from butenes, 309, 392
Di-*ter*-butyl sulphate, reaction with hydrogen sulphide, 463
Dibutyl sulphone, extraction agent, 486
Dicarboxylic acid chlorides, preparation of, 945
Dicarboxylic acids, from diolefins, 698

Dichloroacetic acid, from pentachloroethane, 830
—, reaction with cyclohexene, 313
—, — isopropyl alcohol, 376
—, — propene, 308
asym-Dichloroacetone, from acetone-chlorine reaction, 430
ω,ω-Dichloroacetophenone, from phenylacetylene, 626
Dichloro-*ter*-amyl alcohol, preparation of, 523
o-Dichlorobenzene, as cleansing agent, 790
—, as paint remover, 790
—, as solvent, 543, 546, 790
—, *o*-diaminobenzene from, 787
—, dewaxing agent, 433, 495, 507
—, fluorination of, 792
—, hydrolysis of, 785
—, in analysis of graphite grease, 789
—, in decarbonizing, 790
—, in lubricants, 790
—, reaction with ammonium hydroxide, 787
—, — sulphonyl chloride, 782
p-Dichlorobenzene, *p*-chlorophenol from, 783, 784
—, from benzene, 781
—, in motor fuel, 1039
—, reaction with chloroform, 729
—, — cuprous oxide, 784
—, tri-(2,5-dichlorophenyl) methane from, 729
Dichlorobenzenes, chlorination of, 781
—, in insecticides, 790
1,2-Dichlorobutadiene, polymerization of, 687
2,3-Dichlorobutadiene, from 1,2,3,4-tetrachlorobutane, 686, 687
2,2-Dichlorobutane, preparation of, 452
2,3-Dichlorobutane, solvent for fats, 753
Dichlorobutanes, from butane, 752
—, pyrolysis of, 678
1,2-Dichlorobutene, from butadiene, 685
—, from monovinylacetylene, 687
—, polymerization of, 685
1,4-Dichlorobutene, from butadiene, 685
—, polymerization of, 685
1,4-Dichloro-2-butene, dechlorination of, 685
3,4-Dichloro-1-butene, reaction with potassium hydroxide, 680, 681
Dichlorobutenes, monovinylacetylene from, 685
Dichloro-*ter*-butyl alcohol, epichlorohydrin from, 523
—, from chloroisobutene, 521
—, β-methyl glycerol from, 523
1,2-Dichlorocyclohexane, preparation of, 767
—, pyrolysis of, 767, 768
Dichlorocyclopropane, formation of, 761
1,10-Dichlorodecane, reaction with diamylamine, 810
Dichlorodiacetylene, from hexachlorobutane, 510
Dichlorodialkylether, from olefins, 628
β,β′-Dichlorodiethyl ether, N-alkyl morpholines from, 583
—, as extraction agent, 30, 31, 515, 529, 530
—, as solvent, 30, 43, 727
—, dioxane from, 579
—, di-β-phenylethyl ether from, 529
—, divinyl ether from, 528
—, ethylene oxide from, 551
—, for absorption of olefins, 163
—, in dewaxing, 530
—, preparation of, 528
—, reaction with alkalies, 528
—, — ammonia, 583
—, — aniline, 528, 583
—, — phenols, 528
—, — phenylhydrazine, 583
—, — sodium polysulphide, 528
Dichlorodiethyl sulphide, detection of, 619
—, from ethylene, 619
Dichlorodifluoromethane, as refrigerant, 737, 738
—, from carbon disulphide, 737
—, from carbon tetrachloride, 733, 734
—, from difluoromethane, 734, 735
—, from monofluorotrichloromethane, 737
—, diluent, fluorination of benzene, 792
—, in fractional crystallization, 31
—, in charging cream, 739
β,β′-Dichlorodiisopropyl ether, preparation of, 530
2,3-Dichlorodioxane, preparation of, 581
2,3-Dichloro-1,4-dioxane, reaction with trimethylene glycol, 549
Dichloroethane, determination of, 744
—, extractant for sulphur, 745
—, hydrolysis of, 797
—, reaction with ammonia, 808, 809
—, — *sym*-dichloroethylene, 811
—, — hydrogen fluoride, 747
—, — oleic acid, 815
—, — trichloroethylene, 811
—, — vinyl chloride, 811
—, solvent for naphthalene, 745
—, use in cracking, 114
—, uses for, 745
Dichloroethylene, as extraction agent, 1245
—, preparation of, 711
Dichlorofluoromethane, monochlorodifluoromethane from, 737
1,4-Dichlorohexane, preparation of, 766
1,3-Dichloroisobutane, in de-inking paper, 753
Dichloromethane, entropy chart, 1337
—, from carbon tetrachloride, 807
—, *see* Methylene chloride
1,3-Dichloro-2-methylbutane, formation of, 513
2,3-Dichloro-2-methylbutane, formation of, 513
1,2-Dichloro-2-methylpropane, hydrolysis of, 797
1,3-Dichloro-2-methylpropane, use in dewaxing oils, 753
Dichloropentamethylenetetramine, reaction with benzene, 779
Dichloropentane, in varnish remover, 755
—, *see also* 1-Amylene dichloride
Dichlorophenyl methane, reaction with ethers, 345
Dichloropropane, from cyclopropane, 761
1,2-Dichloropropane, as fumigant, 751
—, *see also* Propene dichloride
Dicyanodiamide, as antiknock, 1018
Dicyanoperylenes, as antioxidants, 918
Dicyclohexene, antiknock properties of, 1027, 1028
1,1′-Dicyclohexene, reaction with ozone, 902
Dicyclohexyl oxalate, from cyclohexanol, 406
Dicyclopentadiene, bromination of, 700
—, decomposition of, 652
—, demethanation of, 156
Dielectric constant, definition of, 789
Dielectrics, ceresin in, 1255
—, from chlorobenzenes, 782
—, from chloroform, 728
—, from ethylene dichloride, 789
—, from pentachlorobiphenyl, 789
—, from trichlorobenzene, 789
Die lubricants, preparation of, 731
Diesel fuel, cetene as reference standard, 1033, 1034
—, from carbon monoxide and hydrogen, 1250
—, from cracked distillates, 126
—, Kogasin as, 1253
—, mesitylene as reference standard, 1033
Diethanolamine, for absorption of olefins, 164
—, gum inhibitor, 915
—, in washing textiles, 575
—, morpholine from, 583
—, preparation of, 567
—, reaction with calcium bromide, 572
—, — trinitrotoluene, 570
Diethers, from ethylene glycol, 889
Diethinylcyclobutane, preparation of, 705
Diethylamine, *ter*-amines from, 809
—, catalyst, condensation of aldehydes, 889
—, in preparation of hydroxyalkylcellulose, 559
—, reaction with ethylene chlorohydrin, 527
Diethylaminoethanol, preparation of, 568
Diethylaniline, preparation of, 346
Diethylbenzene, from ethylbenzene, 208
o-Diethylbenzene, in gasoline, 144
Diethyl carbonate, solvent for acetylene, 169
1,2-Diethylcyclohexene, naphthalene from, 94
Diethylene glycol, dehydration agent, 538
—, fatty acid esters, toxicity of, 549
—, from ethylene glycol, 544, 577
—, in heat transfer media, 539
—, in pressure transfer media, 539
—, in tobacco, 546

Diethylene glycol, in wetting agents, 1076
—, reaction with ethylene oxide, 558
—, — nitric and sulphuric acids, 546
—, sodium salt, reaction with hexaethylene glycol, 544, 545
Diethylene glycol butyl ether, as solvent, 546
—, in brake fluid mixtures, 546
Diethylene glycol dinitrate, preparation of, 546
Diethylene glycol ethers, as solvents, 543
Diethylene glycol ethyl ethers, in brake fluid mixtures, 546
Diethylene glycol formal, as solvent, 542, 543
Diethylene glycol isobutyrate, plasticizer for cellulose acetate, 540
Diethylene glycol monoethyl ether, in condensers, 545
Diethylene glycol monoethyl ether, reaction with boric acid, 545
Diethylene glycol propionate, in cellulose compositions, 546
Diethyl ether, as blending agent, 1035, 1038
—, as extraction agent, 300, 1070, 1245
—, catalyst, oxidation of hydrocarbons, 862
—, decomposition of, 334, 335
—, dehydration of, 538, 578
—, estimation of paraffin wax, 1155
—, ethyl alcohol from, 332, 333, 334
—, ethylene from, 334
—, from ethyl alcohol, 330, 331, 332
—, from ethyl chloride, 797
—, from ethylene oxide, 558
—, ignition temperature of, 987, 988, 989
—, in motor fuels, 1039
—, inflammability limits of, 980, 985
—, oxidation of, 335
—, peroxides from, 335, 336, 337
—, reaction with hydrogen chloride, 345
—, solvent for ketene, 435
Diethyl ether-gasoline blends, as motor fuels, 1038
α-Diethyl-ethylene chlorohydrin, preparation of, 520
Diethyl fumarate, reaction with monoethanolamine, 569
Diethyl ketone, as solvent, 681
—, from propionic acid, 446
—, reaction with calcium hypochlorite, 453
—, triethyl carbinol from, 457
Diethyl magnesium, reaction with olefin oxides, 586, 588
Diethyl maleate, antioxidant, 915
Diethyl malonates, alkylated, cyclopentadiene derivatives from, 676
Diethyl oxalate, solvent for acetylene, 169
3,3-Diethylpentane, in shale oil, 33
Diethyl pentasulphide, preparation of, 481, 482
Diethylpinacone, reaction with alum, 678
Diethyl phthalate, decarboxylation of, 952
Diethyl sulphate, ethyl acetate from, 305
—, ethyl alcohol from, 326, 327
—, ethylating agent, 300
—, ethyl ether from, 326
—, formation of, 298-300, 321
—, hydrolysis of, 300
—, reaction with calcium acetylide, 722
—, — hydrogen chloride, 327
—, — monoethanolamine, 568
Diethyl sulphide, from ethylene oxide-potassium thiocyanate reaction, 564
Diethyl thiosulphite, preparation of, 345, 346
Diethyl *o*-tolyl ammonium chloride, 808
Diethyl trisulphide, action on metals, 481
—, oxidation of, 481
—, preparation of, 481
Difluoromethane, from methylene chloride, 734
—, reaction with chlorine, 734, 735
Difluoromonochloromethane, from chloroform, 737
Difuroyl peroxide, reaction with sodium methoxide, 1152
Diglycolic acid, from dioxane, 580
Dihalides, reaction with mercaptans, 485
Dihaloethanes, hydrolysis of, 532
Dihaloperylenes, as antioxidants, 918
Di-*n*-heptyl ketone, from caprylic acid, 446
Di-*n*-heptyl mercury, pyrolysis of, 71
Dihydrobiphenyl, from benzene, 259
Dihydrobenzene, from cyclohexane, 93
Dihydrochaulmoogric acid, use in leprosy treatment, 771, 772
Dihydrodianthrone, catalyst, oxidation of petroleum, 964
Dihydronaphthalene, from disodiumnaphthalene, 958
Dihydronaphthalene, from disodiumnaphthalene, 958
—, naphthalene carboxylic acids from, 958
1,2-Dihydronaphthalene, preparation of, 906
1,4-Dihydronaphthalene, reaction with ethyl hypochlorite, 626
Dihydroxyacetone, antidote for hydrocyanic acid, 434
Dihydroxyanthraquinones, as antioxidants, 918
o-Dihydroxybenzene, from chlorobenzenes, 782
—, *see also* Pyrocatechol
Dihydroxybenzenes, stabilizers for gasoline, 917
3,4-Dihydroxy-*ter*-butylbenzene, as antioxidant, 916
Dihydroxybutyric acid, from crotonic acid, 547
1,2-Dihydroxy-4-cyclohexylbenzene, as antioxidant, 916
Dihydroxydimethylperoxide, from methane, 882
β,β′-Dihydroxyethyl sulphide, from ethylene oxide, 463
Dihydroxyfluorenes, as antioxidants, 918
Dihydroxynaphthalenes, as antioxidants, 918
1,5-Dihydroxynaphthalene, reaction with ethanolamine, 569
Dihydroxyperylenes, antioxidants, for gasoline, 918
Di-β-hydroxypropylamine, preparation of, 585
β-γ-Dihydroxypropylaniline, reaction with ethylene oxide, 561
1,2-Dihydroxy-4-propylbenzene, as antioxidant, 916
Di-iodofluoromethane, from iodoform, 737
—, reaction with ammonia, 737
Di-iodomethane, reaction with ethers, 345
Diisoamyl ketone, from isopentane, 445
Diisobutylene, decomposition of, 184
—, from isobutene, 386, 641, 642, 1300
—, hydrogenation of, free energy change, 1300
—, —, —, effect of temperature on, 1300
—, molal entropy, 1291
—, oxidation of, 895
—, pyrolysis of, 87
—, reaction with benzene, 592
—, — phenol, 604
Diisocrotyl, from diisobutylene, 87
Diisopropylamine, formation of, 428
Diisopropylbenzene, preparation of, 208, 382, 383, 402, 592
Diisopropyl ether, formation of, 363, 377, 530
—, reaction with acetic acid, 377
2,4-Diisopropylphenylisopropyl ether, preparation, 403
Diisopropyl sulphate, diisopropyl ether from, 363
—, preparation of, 305, 358, 361
—, reaction with benzene, 597, 598
—, — hydrogen peroxide, 381
Diisopropyltoluene, from toluene, 382
Diketene, preparation of, 441
—, reaction with aniline, 442
Diketones, reaction with nitroparaffins, 1096
1,3-Dimethoxybenzene, reaction with isobutene, 606
Dimethyl acetal, formation of, 714
Dimethylacetylene, preparation of, 722
β,β-Dimethylacrolein, preparation of, 444
unsym-Dimethylallene, polymerization of, 650
Dimethylamine, reaction with pentene-1,2-oxide, 589
—, promoter, esterification of *ter*-butanol, 412
1-Dimethylaminopentanol-2, preparation of, 589
Dimethylaniline, amine nitrate from, 623
—, as antiknock, 1018
—, in sulphation of alcohols, 1085
—, isoamylene from, 623
—, production of, 311
Dimethylanthracene, from toluene, 208
2,6-Dimethylanthracene, from *p*-xylene, 96
—, pyrolysis of, 96
Dimethyl-N-anthranilic acid, use in hydrogen sulphide removal, 458
2,6-Dimethylbenzoquinone, from mesitylene, 954
2,2′-Dimethylbiphenyl, from toluene, 260

Dimethyl bis (diethylmethyl) lead, preparation of, 823
1,3-Dimethylbutadiene-1,3, preparation of, 173
Dimethylbutadiene, reaction with nitrogen trioxide, 697
2,3-Dimethylbutadiene, co-polymerization with chloroprene, 681, 682
2,2-Dimethylbutane, formation of, 601
2,3-Dimethylbutane, detonation of, 1017
—, in petroleum, 32
2,2-Dimethylbutanol, from 2-methylpentene-1, 388
3,3-Dimethylbutanol-2, dehydration of, 401
Dimethylchloramine, reaction with ketene, 440
Dimethylcyclohexane, action of aluminum chloride on, 206
—, cracking of, 111
—, from ethylcyclohexane, 205
—, pyrolysis of, 93, 185
1,2-Dimethylcyclohexane, from petroleum, 34
1,3-Dimethylcyclohexane, from cyclohexane, 205
1,4-Dimethylcyclohexane, autoxidation of, 907
—, in gasoline, 144
Dimethylcyclohexanol, reaction with phosphorus pentachloride, 775
1,3-Dimethylcyclohexene, reaction with bromine, 775
Dimethylcyclopentane, in gasoline, 34
Dimethyldicyclopentyl, from cyclohexane, 205
—, from decalin, 206
1,4-Dimethyl-2,3-diethyl-1,3-butadiene, from diethylpinacone, 678
Dimethyl-*p*-dioxane, from acetaldehyde, 579
Dimethyldioxane, from propene oxide, 579
Dimethyl ditelluride, formation of, 50, 51
Dimethyl ether, catalyst, oxidation of hydrocarbons, 862
—, chlorination of, 529
—, from methyl chloride, 796
—, methyl chloride from, 794
—, reaction with benzal chloride, 794
—, — chloroform, 729
Dimethylethyl acetic acid, preparation of, 819
***unsym*-Dimethylethylene, from di-*ter*-butylethylene, 87**
Dimethylethylene, from isobutyl bromide, 806
***a*-Dimethyl-ethylene chlorohydrin, preparation of, 520**
Dimethyl glycolic aldehyde, from 2-butene, 897
Dimethyl glyoxal, from 2-butene, 897
3,3-Dimethylheptane, in shale oil, 33
2,5-Dimethylhexane, pyrolysis of, 72
—, *p*-xylene from, 73
Dimethyl-*n*-hexylcarbinol, preparation of, 450
4,4-Dimethyl-3-isopropylbutene-2, formation of, 411
Dimethylketoxime, from propyl pseudonitrole, 1094
Dimethylmorpholine, preparation of, 585
Dimethyl mercury, formation of, 50
—, reaction with mercuric bromide, 51
Dimethylnitrosoamine, in fuels, 1098
2,7-Dimethyloctane, *m*-methylisopropylbenzene from, 73
—, nitration of, 1090
2,7-Dimethyloctene, preparation of, 807
2,2-Dimethylpentane, from petroleum, 32
4,4-Dimethylpentanol-2, dehydration of, 400
3,4-Dimethylpentan-2-one, *see* Methylisopropylacetone
3,3-Dimethyl-1-pentene, from carbon monoxide and hydrogen, 1243
4,4-Dimethylpentene-1, preparation of, 400
—, reaction with hydrogen bromide, 318
4,4-Dimethylpentene-2, preparation of, 400
Dimethylpentenol, reaction with hypochlorous acid, 521, 522
Dimethyl phthalate, decarboxylation of, 952
—, methyl benzoate from, 952
1,2-Dimethyl-1,3-propanediol, from 2-butene, 624
1,2-Dimethylpropanol-1, dehydration of, 400
Dimethylquinoline, from anthracene oil, 839
—, from petroleum, 834, 838
Dimethyl sulphide, in petroleum, 454
1,1′-Dinaphthyl, perylene from, 208
2,2′-Dinaphthyl, from naphthalene, 208
—, perylene from, 209
Dinaphthylene oxides, as antioxidants, 918
Dinaphthyl ethers, formation of, 500
Dinitrate, from tetramethylethylene, 621, 622
Dinitrite, from tetramethylethylene, 621
***m*-Dinitrobenzene, extraction with butanone, 1148**
1,1,1-Dinitrochloroethane, formation of, 451
4,6-Dinitro-3-ethyloltoluidine, preparation of, 570
Dinitrotetramethylethane, preparation of, 621
Dinitrotoluene, separation from trinitrotoluene, 496
Diolefins, absorption by cuprous chloride, 391
—, adsorption of, 255
—, condensation with acid anhydrides, 687-690
—, — acids, 688, 690, 691
—, — aryl halides, 691
—, — maleic anhydride, 679
—, — quinones, 175, 679, 688, 689
—, dicarboxylic acids from, 698
—, effect of pressure on, 666
—, — lead tetraethyl on, 1019, 1020
—, effect on gasoline, 909
—, estimation, 698-700
—, halogenation, 683, 690, 700
—, in gasoline, 913
—, oxidation of, 666
—, polymerization of, 88, 170, 310, 385, 649-654
—, pyrolysis of, 88
—, reaction with alkali metals and amines, 698
—, — diazotized aniline, 700
—, — formic acid, 698
—, — halogen acids, 699
—, — mesityl oxide, 175
—, — sulphur chloride and oxygen, 696
—, — sulphur dioxide, 176
—, reduction to monolefins, 698
—, removal from gaseous mixtures, 359
—, separation from amylenes, 310
—, solvent action of dioxane on, 581
—, use in peroxidation, 923
Diols, dehydration of, 548
Dioxane, chlorination of, 581
—, oxidation of, 580
—, pharmacological properties of, 580
—, preparation of, 551, 578, 579
—, pyrolysis of, 580
—, reaction with arsenic trichloride, 580
—, solvent power of, 580
—, utilization of, 581
1,3-Dioxolane, preparation of, 582
Dioxalanes, from alkylacetylenes, 724
Dioxalones, from alkylacetylenes, 724
Dipentene, reaction with formaldehyde, 624
—, — selenious acid, 446
Diphenylamines, as antioxidants, 940
—, as heat-transfer medium, 194
—, from benzene, 260
—, from bromobenzene, 787
—, from phenyl chloride, 810
—, in esterification of olefins, 316, 318
***p*-Diphenylbenzene, from benzene, 95**
Diphenylbutadiene, formation of, 649
Diphenylcyclohexane, from benzene, 207
Diphenyl dinitroethane, from stilbene, 621
γ,γ′-Diphenyldipropyl ether, preparation of, 529
Diphenylene ditelluride, as antiknock, 1018
Diphenylene oxide, reaction with chlorinated paraffins, 758
1,2-Diphenylethane, from toluene, 260
Diphenyl ether, as heat-transfer medium, 861
—, from phenol, 788, 789
—, from potassium phenolate-ethylene chloride reaction, 500
—, in dehydrogenation of alcohols, 420
—, in high-temperature lubricant, 194
—, reaction with chlorinated paraffin, 818
Di-β-phenylethyl ether, preparation of, 529
Diphenylguanidine, adsorption by carbon black, 252
—, accelerator, production of carbon black, 239
Dipole moment, definition of, 441
Diphenylmethane, benzophenone from, 943, 957
—, in dehydrogenation of alcohols, 420
—, molal entropy, 1289
—, oxidation of, 943, 957
Diphenyl oxide, as heat-transfer agent, 860
Diphenyl sulphide, from benzene, 468

Dipropenyl, from diallyl, 88
Dipropyl ketone, decomposition of, 450
—, ethyl dipropyl carbinol from, 452
—, photochemical decomposition, 449
—, preparation of, 443
—, solvent, 443
Dipropyl ether, dewaxing agent, 495
Disodium glycolate, dehydrating agents, 330
Disodium naphthalene, dihydronaphthalene from, 958
Disodium phosphate, in fermentation of sucrose, 547
Disodium thioglycolate, in olefin estimation, 1144
Dispersing agents, by sulphonation of ethers, 825
—, — oxygenated hydrocarbons, 1061
—, ethanolamine salts as, 575
—, ethylene oxide in preparation of, 566
—, for graphite, 576
—, from mercaptans, 472
—, hydroxyethyl ethers as, 558
—, naphthenic acids in, 1112, 1117
—, naphthenic alcohols as, 1120
—, sulphuric acid esters in, 1112
—, urethans as, 569
Disulphides, antioxidants, for white oils, 937
—, effect on color stability, 454, 456
—, — lead susceptibility, 456, 480, 481, 1031
—, from alkyl sulphur chlorides, 478
—, from mercaptans, 470, 471, 480
—, in insecticides, 1112
—, in petroleum, 454
—, reaction with ammonia and sulphur, 481
Disulpho-butyric acid, formation of, 616
Disulphonic acids, catalyst, esterification of acetylene, 717
Disulpho-propionic acid, formation of, 616, 820
1,3-Dithiane, preparation of, 485
1,4-Dithiocyanobutene, chlorination of, 698
—, from butadiene, 698
Dithionic acid, catalyst, dehydration of alcohols, 410
—, —, hydration of higher olefins, 297, 410
Ditolyl, from toluene, 208
Ditolyl disulphide, flotation agent, 486
Ditolylethane, formation of, 719
Ditolyl mercury, as antioxidant, 938
Divinylacetylene, hydration of, 709
—, hydrogenation of, 709
—, polymerization of, 708, 709
—, preparation of, 704, 708
—, reaction with chlorine, 709
—, — hydrogen polysulphide, 709
—, — thio-*p*-cresol, 709
Divinyl ether, from *β,β'*-dichloroethyl ether, 528
—, from acetylene, 715
—, in anesthesia, 528, 529
—, reaction with acetyl iodide, 612
Dixylylethane, preparation of, 719
Doctor solution, estimation of sulphur, 1156, 1157
Doctor sweetening, defined, 474
Dodecane, from *n*-tetradecane, 1297
Dodecene, from 1-hexene, 1299, 1300
—, from isobutene, 643
—, from propene, 639
—, in kerosene, 145
—, reaction with benzene, 591
n-Dodecyl ammonium thiosulphate, preparation of, 829
Dodecylbenzene, preparation of, 1254
Dodecyl chloride, reaction with sodium thiocyanate, 822
Dodecyl halides, glycol ethers from, 543
n-Dodecyl iodide, reaction with ammonium thiosulphate, 829
Dodecyl mercaptan, reaction with ethylene oxide, 564
Dodecyl thiocyanate, use as insecticide, 822
a-Dodecylthiol, reaction with ethylene chlorohydrin, 526
Driers, fatty acids in, 1115
—, from lead tetra-alkyls, 823
—, from naphthenic acids, 1115
—, from sulphonates, 1081
—, from wax acids, 1055
Drying oils, acetylene in synthesis of, 701
—, by oxidation of petroleum, 1054, 1055
—, from copolymerization of olefins and diolefins, 203
—, from acid sludge, 1055
Dubbs process, of cracking, 117
Dubrovai process, of cracking, 123, 124
Ductility, of asphalts, 1207, 1208
Duo-Sol process, 43
Duprene, definition of, 681
—, *see* Neoprene
Durene, from xylenes, 208
Dust fixatives, preparation of, 1079
Dyes, estimation of benzene with, 1185
—, from chlorobenzenes, 782
—, oil-soluble, preparation of, 1079
—, phthalic anhydride in, 946
—, sulphonated naphthenic acids as, 1117, 1118
—, water-soluble, oil-soluble from, 1079
Dyestuffs, antioxidants for gasoline, 919
—, inhibitors, gum formation, 913

E

Earthenware fragments, catalyst, in Houdry process, 129
Edeleanu extract, for dehydration of isopropyl alcohol, 364
Electric discharge, action on alcohols, 256, 262
—, — esters, 262
—, — gaseous hydrocarbons, 253, 254
—, — kerosene, 253
—, — petroleum hydrocarbons, 255, 256, 262
—, — water, 256
—, ignition, 1001, 1002
—, polymerization by, 631
Electrion oils, preparation of, 260-263
Electrodes, use in cracking methane, 54
Electrolytic chlorination, of benzene, 780
Electromagnetic field, action on acetylene, 267
—, — gasoline, 267, 268
Electromotive force, free energy change from, 1276, 1277
Emulsifiers, natural, in crude petroleum, 1217
Emulsifying agents, alkyl thiosulphates as, 828, 829
—, by sulphonation of ethers, 825
—, calcium sulphonate as, 1074
—, ethanolamine salts as, 575, 1074
—, ethylene glycol ethers as, 543, 558
—, ethylene glycol in, 1114
—, ethylene oxide in preparation of, 566
—, for asphalts, 1216, 1217, 1218
—, formaldehyde in, 891
—, from chlorinated hydrocarbons, 758, 822
—, from ethylene chlorohydrin, 526
—, from mercaptans, 472, 487
—, from petroleum, 1060
—, from tertiary alcohols, 417
—, humic acids used as, 1099
—, kaolin in, 1074
—, mineral oil in, 1079
—, naphthenic acids in, 1112
—, naphthenic acid soaps as, 1114
—, naphthenic alcohols as, 1120
—, polyhydric alcohols in, 1074
—, rosin in, 1114
—, rosin soaps in, 1079
—, sulphates as, 1085, 1086
—, sulphonaphthenic acids as, 1118
—, sulphonated castor oil in, 1074
—, sulphonic acids as, 1074, 1075, 1079
—, sulphuric acid esters in, 1112
—, wax acids as, 978
Emulsions, aquolysis of, 133
—, breaking of, 10, 757, 946, 947
—, in crude oil, 10
—, stabilizers for, 584
Enamels, preparation of, 728
Endothermic reactions, in cracking process, 103
Energy, of activation, dehydrogenation of cyclohexane, 92
—, —, of cracked naphtha, 102
—, —, of halogen-olefin reactions, 491

Energy, of activation, of mazout, 103
—, —, of petroleum fractions, 102
—, —, of propane, 58
—, —, pyrolysis of benzene, 95
Enthalpy, definition of, 1306
—, *see also* Heat content
Enthalpy diagrams, determination of, 1332-1335
Enthalpy-pressure-temperature relations, of benzene, 1333
—, of crude oil, 1334, 1335
—, of naphtha, 1333, 1334
—, of *n*-pentane, 1333, 1334
Enthalpy table, for methane, 1337
Entropy, definition of, 1273-1275, 1306
—, molal, of acetylene, 1282-1284
—, —, of aromatics, 1289, 1290

—, relation to free energy, 1275
—, — equilibrium constant, 50
—, — heat capacity, 1273, 1306
—, — heat of reaction, 50
Entropy change, effect of structure on, 1286, 1288-1293
—, evaluation from heat capacity, 1278, 1279
—, — from specific heat, 1277
—, free energy change from, 1276, 1277
—, isomerization *n*-butane to isobutane, 1282
Entropy chart, of dichloromethane, 1337
Entropy-heat content relations, 1341-1343
Entropy table, for methane, 1337
Entropy-temperature relations, 1335-1341
Entropy units, definition of, 1280
Eosin, catalyst, cyclohexene-oxygen reaction, 898
Epichlorohydrin, preparation of, 523
—, uses of, 524
Epinephrine, effect on heart, 1269
Eponit-Ratibor, to clarify wines, 232
1,8-Epoxynaphthalene, as antioxidant, 918
Equations of state, 1319
Equilibrium constant, free energy change from, 1276, 1277
—, relation to free energy change, 50, 1275, 1276
—, — entropy, 50
Esters, action of electric discharges on, 262
—, by oxidation of petroleum, 962, 963
—, from aldehydes, 889
—, from carbon monoxide and hydrogen, 1223
—, from paraffin wax, 971, 972
—, from wax acids, 970
—, halogenated, reaction with olefins, 613, 614
—, in co-polymerization of chloroprene, 681, 682
—, pyrolysis of, 341
—, solvents for asphalts, 1202
Esterification, of alcohols, 1080, 1081, 1118-1120
—, of ethylene glycol, 540, 541
—, of phthalic anhydride, 541
—, of polyglycols, 545
—, of polyhydric alcohols, 541
—, of polymethylene alcohols, 1118, 1119
—, of wax acids, 975
Ethane, acetic acid from, 856, 857, 858
—, acetylene from, 168
—, acids from, 871, 872
—, action of glow discharge on, 257
—, — silent discharge on, 257
—, alcohols from, 857, 858, 871, 872
—, aldehydes from, 856-858, 871, 872
—, analysis of, 1130, 1131
—, and propane, extraction agent, 42
—, as motor fuel, 1040
Ethane, bromination of, 747
—, carbonization of, 56
—, chlorinated, properties of, 743
—, —, uses for, 744, 745
—, chlorination of, 741
—, combustion of, 52
—, depressant, decomposition of ethylene oxide, 554
—, effect on viscosity of crystal oil, 15
—, entropy-temperature relations, 1336, 1339
—, ethyl alcohol from, 856, 857, 858
—, ethylene from, 151
—, —, free energy change, 1284
—, fluorinated, properties of, 748, 749
—, fluorination of, 747
—, formaldehyde from, 856, 857
—, formic acid from, 856, 857, 858
—, free energy of formation, 1225
—, —, effect of temperature on, 1294
—, from butane, 62, 64, 201
—, from carbon monoxide and hydrogen, 1226, 1241, 1242
—, from cracking gas, 301
—, from cracking operations, 140
—, from cyclohexane, 93
—, from cyclopentane, 90
—, from ethyl alcohol, 331, 350, 357
—, from ethylene oxide, 554
—, from free radicals, 53
—, from gas oil, 140
—, from *n*-hexane, 71
—, from methane, 158, 257
—, from methyl ethyl ketone, 449
—, from methyl propyl ketone, 450
—, from natural gases, 22
—, from *n*-nonane, 72
—, from *n*-pentane, 68
—, from pentene, 86
—, from propene, 80
—, from toluene, 260
—, heat of combustion, 15
—, ignition of, 1001
—, ignition temperature of, 987, 988, 989, 992, 993
—, inflammability limits of, 984
—, in petroleum gases, 21
—, methyl alcohol from, 856, 857, 858
—, Mollier diagram, 1341-1343
—, nitration of, 1087
—, oxidation of, 846-848, 850, 856-858, 869, 871-873, 1129, 1130
—, pyrolysis of, 55, 56, 148-150, 151, 158
—, resins from, 257, 258
—, separation from ethylene, 1140
Ethane-acetylene, azeotropic mixture of, 1140
Ethane bromides, hydrolysis of, 805
Ethane chlorides, narcotic effect of, 745
—, as dry cleaning agents, 745
—, as refrigerants, 745
—, in insecticides, 745
—, in refining lubricants, 744, 745
sym-Ethane disulphonic acid, from nitroethane, 1096
Ethanethiol, reaction with ketene, 438
Ethanol, *see* Ethyl alcohol
Ethanolamine, catalyst, reaction of alcohols and alkene oxides, 568
—, —, — ethylene dichloride and sodium polysulphide, 499
—, condensation of, 568
—, dehydrogenation of, 568
—, dispersing agent, 576
—, from ethylene oxide, 567
—, reactions of, 568, 569
Ethanolamines, absorption of carbon dioxide, 573, 574
—, as reducing agents, 570
—, decomposition of, 570
—, in soaps, 575
—, inhibitors, gum formation, 915
—, reaction with metallic salts, 570
—, — phthalic anhydride, 958
—, — thionyl chloride, 570
—, removal of sulphur from gases, 573, 574
—, sulphuric esters of, uses, 578
Ethanolamine salts, uses, 575

Ether, effect on leucocytosis, 1268
—, flocculating agent for asphalts, 1196
—, fractional extraction of mazout with, 1188
—, from propene, 358
—, purification of, 336
Ether, *see also* Diethyl ether
Ether peroxides, catalysts, reaction of ethylene and sulphur dioxide, 617
Ethers, aliphatic, reaction with acetyl iodide, 611
—, antioxidants for gasoline, 916
—, extractants for asphalts, 1187, 1202
—, formation during olefin hydration, 283
—, from acetals, 715
—, from alcoholates, 825
—, from alcohols, 406, 413, 579
—, from alcohol-vinylacetylene reaction, 705
—, from alkyl halides, 804, 825
—, from chlorohydrins, 524, 525
—, from esters, 406
—, from olefins, 331, 406
—, peroxides from, 380, 381
—, reaction with alcohols, 715
—, — alkyl halides, 345
—, rearrangement of, rules for, 825, 826
—, solubilities of, in sulphuric acid, 379
Ethionic acid, from ethylene, 321, 1082
4-Ethoxy-2-butyne, reaction with ethyl alcohol, 705
2-Ethoxy-1,1-dimethylethanol, from isobutene oxide, 548
2-Ethoxyethanol, reaction with ketene, 435
2-Ethoxyethyl acetate, preparation of, 435
2-Ethoxyethyl caprylate, as plasticizer, 543, 544
5-Ethoxymorpholine, preparation of, 561
Ethyl acetate, estimation of paraffin wax, 1155
—, from ethyl alcohol, 337, 341, 421
—, from ethylene, 304, 305
—, in stabilizing carbon tetrachloride, 730
—, precipitant for asphaltenes, 1192
—, pyrolysis of, 341, 421, 423
Ethyl acetoacetate, reaction with acetylene, 721
p-Ethylacetophenone, from benzene, 439
Ethylacetylene, from methylallene, 88
—, reaction with acetic acid, 718
Ethyl alcohol, absorbent for butadiene, 174
—, acetal from, 339
—, acetaldehyde from, 337-340, 348, 349, 844, 878, 879
—, acetic acid from, 338, 339, 421, 844
—, acetone from, 340, 421, 422
—, acetone in, 327
—, activity in sulphuric acid, 343, 344
—, aromatics from, 342
—, as antiknock, 1016, 1017
—, as chemical intermediate, 330
—, azeotropic distillation of, 328, 329
—, azeotropic mixture with isopropyl alcohol, 369
—, *n*-butanol from, 337
—, butyl acetate from, 338
—, by fermentation, 319
—, catalyst, reaction of ethylene dichloride and ammonia, 497
—, combustion of, 1004, 1005
—, dehydration of, 328, 329, 330, 1051
—, dehydrogenation of, 288, 337, 348, 878
—, diamyl ether from, 337
—, dibutyl ether from, 337
—, diethyl ether from, 330, 331, 332
—, electrical decomposition of 256, 347
—, estimation of, 353, 354, 355
—, estimation of paraffin wax, 1155
—, 2-ethoxy-1,1-dimethylethanol from, 548
—, ethyl acetate from, 337-341, 421
—, ethyl hypochlorite from, 626
—, ethylsulphuric acid from 343
—, ethyl xanthate from, 355
—, explosive characteristics of, 1011
—, extraction agent for asphalts, 1188, 1200
—, — diolefin bromides, 1144
—, — petroleum sulphonates, 1070, 1071
—, — yellow zein, 496
—, flash point of, 988
—, formaldehyde from, 337, 879
Ethyl alcohol, from carbon monoxide and hydrogen, 319, 1305
—, —, free energy change, 1305
— from diethyl sulphate, 326, 327
—, from ethane, 856-858, 872
—, from ether, 332, 333, 334, 421
—, from ethyl acetate, 421
—, from ethylene, 282-291, 319, 322, 323, 552
—, —, free energy change, 1302, 1303
—, from ethylsulphuric acid, 326, 327
—, from hydrocarbons and steam, 269
—, from pentane, 859
—, gels with, 330
—, hexanol from, 341, 347
—, hydrogenating agent, 347
—, hydrogen from, 339-341, 347, 348, 352
—, in anti-freeze mixtures, 374
—, in coating compositions, 353
—, in demulsifying agents, 1075
—, inflammability limits of, 980, 981, 982
—, in fuels, 319, 330
—, inhibitor, dechlorination of tetrachloroethane, 805
—, in insecticides, 790
—, in rubber cement, 374
—, octane number of, 1028
—, oxidation of, 844, 872, 879, 880
—, pentanol from, 347
—, propionic acid from, 339
—, pyrolysis of, 155, 173, 331, 339-342, 347-353, 551
—, reaction with acetone, 443
—, — alkali hydroxides, 342
—, — alkali metals, 342
—, — aluminum, 342, 343
—, — amines, 346, 347
—, — carbon monoxide, 339
—, — chlorine, 626
—, — chlorine and cinnamic acid, 627
—, — 4-ethoxy-2-butyne, 705
—, — ethylsulphuric acid, 332
—, — hydrogen chloride, 345, 742
—, — ketone cyanohydrin, 451
—, — piperidine, 346
—, — platinic chloride, 628
—, — sodium phenolate and carbon monoxide, 957
—, — sulphuric acid, 343
—, — trichloroacetyl glycols, 541
—, — vinylacetylene, 706
—, — zinc sulphate, 878
—, refining montan wax with, 353
—, sodium acetate from, 342
—, solvent properties of, 319, 353, 568, 681
—, to convert gels into sols, 560
—, toluene from, 173
Ethyl alcohol-gasoline, blends, as motor fuel, 1034-1038
Ethylamine, reaction with dibiphenylene ethylene, 615
Ethylaniline, preparation of, 346
—, reaction with butadiene and lithium, 698
Ethyl atropate, preparation of, 451
Ethylbenzene, action of aluminum chloride on, 208
—, benzene from, 96, 208
—, diethylbenzene from, 208
—, effect of lead tetraethyl on, 1022
—, from benzene, 206, 207
—, from *n*-octane, 73
—, from toluene, 208
—, from vinylcyclohexane, 93
—, hydrogen from, 96
—, in petroleum, 34
—, methane from, 96
—, molal entropy, 1289
—, naphthalene from, 96
—, olefins from, 96
—, oxidation of, 942, 943
—, pyrolysis of, 95, 96, 156, 159
—, reaction with acetylene, 719
—, styrene from, 96, 159
—, toluene from, 96
—, triethylbenzene, from, 208
Ethyl benzoate, from diethyl phthalate, 952

Ethyl blending chart, definition of, 1031
Ethyl bromide, catalyst, for Grignard reaction, 772
—, from ethyl alcohol, 345.
—, from ethylene, 304
—, reaction with mercuric fluoride, 748
Ethyl *n*-butyl ketone, preparation of, 589
Ethyl butyrate, use in dewaxing, 353
Ethylcellulose, preparation of, 745
Ethyl chloride, dechlorination of, 805
—, dehydration agent for isopropyl alcohol, 364
—, dewaxing agent for lubricating oils, 738, 739
—, estimation of, 744
—, from ethyl alcohol, 345, 742
—, from ethylene, 301, 302, 304, 305, 742
—, from still gases, 741
—, hydrolysis of, 796, 797
—, in insecticides, 745
—, in refrigerants, 745
—, purification of, 303
—, reaction with ammonia, 808
—, — aniline, 808
—, — cellulose, 745
—, — *α*-naphthylamine, 808
—, — sorbitol, 826
—, — *o*-toluidine, 808
Ethyl chlorosulphinate, preparation of, 346
Ethyl chlorosulphonate, catalyst, reaction of ethylene and hydrogen chloride, 301
Ethyl cyanide, in stabilizing carbon tetrachloride, 730, 731
Ethylcyclohexane, benzene from, 93
—, butadiene from, 93
—, dimethylcyclohexane from, 205, 206
—, from petroleum, 31, 34
—, from styrene, 1154
—, from vinylcyclohexane, 93
—, hydrogen from, 93
—, isomerization of, 205, 206
—, methane from, 93
—, pyrolysis of, 91, 93
—, toluene from, 93
trans-2-Ethylcyclohexanol, preparation of, 589
2-Ethylcyclohexene, oxidation of, 900
Ethylcyclohexyl malonate, preparation of, 773
Ethyldipropyl carbinol, preparation of, 452
Ethylene, absorption by *ter*-butyl hypochlorite, 627
—, — body, 1267
—, — cuprous salts, 163, 164
—, acetic acid from, 629
—, acetylene from, 79, 160, 166, 167
—, action of silent discharge on, 258
—, adsorption by carbon, 324
—, anthracene from, 77, 186
—, as anesthetic, 1256-1261
—, as motor fuel, 1040
—, benzene from, 77, 186
—, butadiene from, 78, 172, 258, 637
—, butene from, 258, 636, 639
—, carbon monoxide from, 622
—, carbyl sulphate from 321, 1081, 1082
—, combustion of, 52, 241, 1001, 1003-1005, 1010
—, dichlorodiethyl sulphide from, 619
—, diethyl sulphate from, 321
—, esterification of, 304, 305, 359
—, estimation of, 1141, 1142, 1259
—, ethionic acid from, 321, 1082
—, ethyl alcohol from, 322, 323
—, —, free energy change, 1302, 1303
—, ethylene glycol from, 627
—, ethylene glycol dinitrate from, 621
—, ethylene glycol molybdate from, 628
—, ethylene glycol nitrate nitrite from, 622
—, ethyl ether from, 322, 323
—, ethylsulphuric acid from, 321, 322
—, explosive properties, 77, 1257, 1258
—, from acetylene, 719
—, from allyltoluene, 96
—, from benzene, 207
—, from *n*-butane, 62-64
—, from carbon dioxide and hydrogen, 1241
—, from carbon monoxide and hydrogen, 1223, 1241
—, from chlorocyclohexene, 172
—, from cracked tar, 155
Ethylene, from cracking gas, 301, 302
—, from cyclohexane, 92, 93, 185
—, from cyclopentane, 90
—, from dibromoethane, 805
—, from ethane, 56, 57, 151
—, —, free energy change, 1284
—, from ether, 334
—, from ethyl acetate, 421
—, from ethyl alcohol, 155, 173, 331, 340, 551
—, from ethylidene bromide, 805
—, from gas oil, 140
—, from gasoline, 136
—, from heptane, 71, 154
—, from isobutane, 67
—, from isobutene, 85
—, from kerosene, 154, 155, 253
—, from ketene, 437
—, from ketones, 449, 450
—, from Kogasin II, 155
—, from methane, 53, 54, 158, 166, 218, 257
—, from 1-methylcyclohexene, 172
—, from methylene radicals, 53, 438
—, from oils, 131
—, from paraffin wax, 138
—, from peat tar, 155
—, from *n*-pentane, 68
—, from pentenes, 86
—, from petroleum hydrocarbons, 253, 254
—, from potassium ethylene trichloroplatinate monohydrate, 628
—, from propane, 58-61, 80, 149, 151, 153, 169
—, from *n*-propyl alcohol, 173
—, from tetrahydrobenzene, 93
—, from toluene, 260
—, from vinyl radical, 75
—, hexene-1 from, 258
—, hydration of, 282-291
—, —, free energy change, 283, 284, 290, 1302, 1303
—, —, —, effect of temperature on, 1302, 1303
—, —, heat, 287
—, hydrogen from, 79
—, ignition temperature of, 987-989
—, inflammability limits of, 980, 985
—, in heat-transfer media, 539
—, inhibitor, decomposition of ketene, 437
—, —, pentane-chlorine reaction, 493
—, in pressure-transfer media, 539
—, iodoalkyl nitrate from, 629
—, isobutane from, 637
—, lubricating oil from, 210
—, naphthalene from, 77, 186
—, *α*-nitroethyl nitrate from, 622
—, oxalic acid from, 622
—, oxidation of, 551, 844, 851, 894, 896, 897
—, —, effect of temperature on, 849
—, —, mechanism, 847, 848, 896
—, pentene from, 639
—, physiological properties, 1257, 1260-1262, 1268, 1269
—, polymerization of, 202, 203, 209, 210, 265, 283, 288, 290, 321, 634, 636-639, 646, 671
—, —, effect of hydrogen, 166
—, —, effect of pressure, 638, 639, 1041
—, pressure-volume-temperature relations, 1322
—, propene from, 636, 639
—, propionic acid from, 446, 626
—, pyrolysis of, 77-79, 166, 184
—, reaction with acetyl chloride, 611, 612
—, — benzene, 594, 595, 597
—, — bromine, 501
—, — butadiene, 186
—, — *ter*-butyl hypochlorite, 518
—, — carbon monoxide, 626, 893
—, — chlorine, 492-494
—, — chloromethyl acetate, 613
—, — N-chlorourea, 515, 516
—, — coal-tar distillates, 209, 593
—, — cracked gas, 1252, 1253
—, — cracked gasoline, 1252, 1253
—, — cyclohexane, 601, 602
—, — ethylene chlorohydrin, 529
—, — ethylsulphuric acid, 298
—, — with halogen acids, 300

Ethylene, reaction with hydrogen chloride molybdic anhydride complex, 628
—, — hydrogen peroxide, 897
—, — hypochlorous acid, 515-520
—, — iodine, 505
—, — isobutane, 599, 601
—, — isopentane, 599
—, — mercuric nitrate and iodine, 629
—, — metal hydroxide, 894
—, — methylcyclohexane, 599
—, — methylcyclopentane, 599
—, — naphthalene, 209, 210, 594
—, — nitric acid, 622
—, — nitrogen tetroxide, 620
—, — oxygen and water, 534
—, — phenol, 605
—, — phosgene, 609, 611
—, — phosphoric acid, 323
—, — potassium hydroxide, 629
—, — propane, 601
—, — steam, 271
—, — stearic acid, 588
—, — sulphur chloride and sodium polysulphide, 618, 619
—, — sulphur dioxide, 617
—, — sulphur mònochloride, 619
—, reaction with sulphuric acid, 161, 298, 319-325, 343, 344, 391, 1081, 1082, 1141, 1142
—, —, effect of concentration, 321
—, —, effect of pressure, 321, 322
—, —, effect of temperature, 321
—, reaction with tetralin, 209
—, — 2,2,4-trimethylpentane, 599
—, removal from gas mixtures, 161-164, 327, 328
—, resins from, 618, 619
—, separation from ethane, 1140
—, — propene, 163
—, sulphinic esters from, 617
—, sulphones from, 617
—, tars from, 656
—, toluene from, 77, 186
—, xylene from, 186
Ethylene-aluminum chloride, catalyst, polymerization of cracked distillates, 214
Ethylene bromide, *see* Ethylene dibromide
Ethylene bromohydrin, ethylene glycol from, 532
—, from ethylene oxide, 565
—, reaction with carbon dioxide, 532
Ethylene chloride, *see* Ethylene dichloride
Ethylene chlorohydrin, acrylic acid from, 527
—, as insecticide, 519
—, β,β′-dichloroethyl ether from, 528
—, effect on plant growth, 519
—, ethylene glycol from, 532
—, ethylene oxide from, 550
—, extraction agent for butadiene, 174
—, from ethylene, 515-520
—, from ethylene dichloride, 517, 518
—, from ethylene glycol, 537
—, from ethylene glycol diacetate, 518
—, from ethylene oxide, 516, 560
—, β-haloethylarsines from, 526
—, hydrolysis of, 518, 519, 533
—, polysulphides from, 526
—, properties of, 519
—, reaction with amines, 527
—, — carbon dioxide and sodium hydroxide, 532
—, — mercaptans, 526
—, — methylol urea, 525, 526
—, — olefins and chlorine, 529
—, — resorcinol, 525
—, — sodium carbonate, 533, 534
—, — thionyl chloride, 525
—, — urea, 525
—, refining petroleum oils with, 519
—, — rosin with, 519
Ethylenediamine, as antiknock, 498
—, corrosion inhibitor, 809
—, desulphurizing agent, 458, 488
—, from ethylene dichloride, 497, 808
—, plasticizing agent for cellulose acetate, 498
—, properties of, 809
—, reaction with zinc chloride, 497
—, — zinc oxide, 497
Ethylenediamine hydrogen chloride, preparation of, 497
Ethylene diarsonic acid, barium salt, preparation of, 505
Ethylene dibromide, crystalline forms of, 730
—, ethylene glycol from, 532
—, from ethylene, 501-505
—, in fire extinguishers, 505
—, promoter, ethylene-bromine reaction, 503
—, reaction with arsenious oxide, 505
—, — carbon dioxide, 532
—, — magnesium, 505, 824
—, — potassium carbonate, 532
—, — potassium phenolate, 505
—, — sodium hydroxide, 532
—, vinyl bromide from, 504, 533
Ethylene dichloride, acetaldehyde from, 533
—, acetylene from, 497
—, azeotropic mixture with water, 500
—, crystalline form of, 730
—, dehydration agent for aliphatic acids, 501, 745
—, — butyl phthalate, 501
—, — isopropyl alcohol, 364
—, dewaxing agent for lubricants, 434, 495
—, ethylene chlorohydrin from, 517, 518
—, ethylene glycol from, 496, 532
—, ethylene glycol diacetate from, 496
—, extraction agent for polymerized hydrocarbons, 397
—, — tetryl, 496
—, — trinitrotoluene, 496
—, — white zein, 496
—, from ethylene, 492-495
—, from ethylene glycol, 537
—, hydrolysis of, 533
—, in acetylation of cellulose, 496
—, in cleaning compositions, 732, 745
—, in dielectrics, 789
—, in fumigants, 566
—, in insecticides, 496

—, preparation of, 507, 547
—, propene glycol from, 547
—, reaction with naphthenic acids, 1112
—, — resins, 217
—, solvent for butadiene, 174
Glycerol benzyl ethers, preparation of, 543
Glycerol monochlorohydrin formal, as solvent, 542, 543
Glycerol trichlorohydrin, preparation of, 507
Glyceryl naphthenate, in insecticides, 1112, 1115
Glyceryl oleate, in insecticides, 1115
Glyceryl trinitrate, reduction of sensitivity to shock, 546
Glycol, extraction of fuels by, 925
—, for absorption of olefins, 163
—, from ethylene, 895
—, from trimethylethylene, 547
—, in refining of gasoline, 930
Glycol diacetate, from ethylene dichloride, 496
Glycol dialkyl ethers, preparation of, 544
Glycol diethers, uses of, 544
Glycol esters, glycols from, 532
—, as absorbents, 738
—, as solvents, 549
Glycol ether esters, as plasticizers, 544

Glycol ethers, applications of, 544, 548, 549, 738
—, preparation of, 548
—, stabilized by triethanolamine, 577
Glycol monosulphuric acid, catalyst, sulphation of ethylene, 323
Glycols, dioxane, from, 578
—, from chlorohydrins, 524
—, from cracked gasoline, 854
—, from ethylene oxide, 557
—, from olefins, 532, 547, 624
—, reaction with aldehydes, 543, 582
—, — ketones, 582
—, — naphthols, 543
Glyoxal, decomposition of, 897, 898
—, from acetylene, 902, 904
—, from olefins, 895, 897
Glyoxal sulphate, preparation of, 829
Gold, catalyst, acetylene-amine reaction, 719
—, —, hydration of ethylene, 291
—, —, oxidation of olefins, 552, 553, 586
—, —, polymerization of acetylene, 705
—, —, pyrolysis of acetals, 715
Gold halide, catalyst, fluorination of alkyl halides, 747
Gold salts, in hydration of acetylene, 712
Gold vanadate, catalyst, hydration of ethylene, 291
Graphite, analysis of, 782
—, catalyst, cyclization of paraffins, 189
—, —, dehydrogenation of acenaphthenes, 955
—, —, pyrolysis of acetylene, 89
—, —, — benzene, 192
—, —, — methane, 180
—, dispersing agents for, 576
—, in lubricants, 731, 1079, 1116
Graphite grease, analysis of, 789
Graphitic carbon, catalyst, pyrolysis of methane, 218
Gravity-index, 1176
Grease, calcium soap in, 1079
—, from spindle oil acid sludge, 1058
—, petrolatum in, 1079
—, sodium mahogany sulphonate in, 1079
Green acids, as demulsifying agents, 1075
—, extraction by β,β'-dichloroethyl ether, 530
—, in insecticides, 1077
—, solubility of, 1065
Green acid salts, as emulsifying agents, 1074
—, separation of, 1071
Green acid soaps, as extraction agents, 1071, 1072
Green oil, burning oil from, 242
—, definition of, 242
—, lampblack from, 242
Grignard reagents, alcohols from, 886
—, reaction with aldehydes, 886
—, — ethylene oxide, 564, 565
—, — vinylacetylene, 708
Grozny oil, naphthenes from, 137
Grozny paraffin, cracking of, 138, 195
—, oxidation of, 846
Guaiacol, antioxidant for gasoline, 916
—, polymerization inhibitor, 705
Guanidine, in fungicides, 569
—, reaction with amines, 587
Gum, estimation in gasoline, 910-912
—, — kerosene, 912
—, from cracked gasoline, 1054
—, oxygen content of, 911
Gum acacia, in asphalt emulsions, 1219
Gumbrin, as adsorption agent, 1109
Gum content, effect of cracking on, 107
Gum flux, naphthenic hydrocarbons as, 915
Gum formation, depletion of inhibitors, 913
—, during storage of fuel, 909
—, dyestuffs as inhibitors for, 913
—, effect of chromic acid on, 924
—, — peroxide formation on, 924

—, reaction with aluminum chloride, 198, 200
—, — molybdenum sulphide, 72
—, — nitric oxide, 1091
—, reference standard in knock rating, 1025, 1026, 1027
—, use in alcohol distillation, 329
—, — motor fuel, 1039
1-Heptene, blending octane number of, 1026, 1027
—, from *n*-heptane, free energy change, 1284
—, inflammation temperature of, 899
—, knock rating of, 1026, 1027
—, molal entropy, 1291
—, reaction with hydrogen bromide, 317
3-Heptene, inflammation temperature of, 899
—, oxidation of, 875
Heptenes, effect of tetraethyl lead on, 1021
—, from carbon monoxide and hydrogen, 1243
—, in gasoline, 144
—, oxidation of, 898, 899
Hepten-3-en-2-one, reaction with acetyl chloride, 612
Heptyl alcohol, from petroleum ether, 853
—, reaction with acetic acid, 406
sec-Heptyl alcohol, from olefins, 404
—, solubility in water, 404
sec-Heptyl esters, use as plasticizers with cellulose nitrate, 409
1-Heptyne, preparation of, 722
—, reaction with ozone, 904
Heptynes, effect of tetraethyl lead on, 1021
Hexabromobenzene, from benzene, 790, 791
Hexabromocyclobutane preparation of, 763
Hexabromoethane, preparation of, 747
Hexachlorobenzene, in chlorinated coal, 730
—, fluorination of, 792
Hexachlorobutane, from butene dichloride, 510
Hexachlorobutene-2, from hexachlorobutane, 510
Hexachloroethane, from carbon tetrachloride, 731
—, from ethylene dichloride, 501
—, from perchloroethylene, 742
—, in chlorinated coal, 730
—, reaction with antimony trichloride, 748
Hexachloropropene, preparation of, 812
Hexachloropyrene, oxidation of, 956
6,10-Hexadecadiyne, reaction with ozone, 904
Hexadecane, antioxidant, paraffin oil oxidation, 907
—, autoxidation of, 907
—, reaction with aluminum chloride, 202
Hexadecane-1,2-diol, from hexadecene-1, 548
Hexadecene, from isobutene, 643
—, oxidation by hydrogen peroxide, 548
—, reaction with persulphuric acid, 309
Hexadecylphenyl acetylene, antioxidant, for gasoline, 918
Hexadeuteriobenzene, preparation of, 273, 725
Hexadiene, by pyrolysis of cyclohexane, 93
—, — ethyl alcohol, 173
—, co-polymerization with trimethylethylene, 216
1,5-Hexadiene, *see* Diallyl.
Hexaethylbenzene, from ethylene and cyclohexane, 601, 602
—, from gaseous olefins, 209
Hexaethylene glycol dichloride, reaction with diethylene glycol, sodium salt, 544, 545
Hexafluoroethane, diluent, fluorination of benzene, 792
Hexahydronaphthalene, as blending agent, 1035
Hexamethylbenzene, molal entropy, 1289, 1290
Hexamethylene derivatives, in gasoline, 33
Hexamethylenetetramine, as adsorbent, 885
—, benzoylation of, 888
—, from methane, 264, 882
—, in pickling solution, 890
—, in preparation of resins, 1058
—, in stabilizing carbon tetrachloride, 730, 731
Hexamethylenetetramine, reaction with acetic anhydride, 888
—, structure of, 887, 888
Hexamethylethane, from pentamethylethyl bromide, 759
Hexane, action of silent discharge on, 257
—, aldehydes from, 1014
—, auto-ignition of, 1017
—, combustion of, 1005, 1014
—, cracking of, 111
—, dehydrogenation of, to benzene, 73
—, effect on photochemical decomposition of acetone, 450
—, effect on reaction of hydrogen bromide and allyl acetic acid, 318

—, from hexenol, 173
—, from petroleum ether, 853
sec-Hexanol, from 1-hexene, free energy change, 1303
—, from olefins, 404
—, solubility in water, 404
—, solvent in ozocerite refining, 409
2-Hexanol, preparation of, 388
3-Hexanol, preparation of, 388, 389
2-Hexanone, from 2-nitrohexane, 1094
Hexanitrodiphenylamine, as antiknock, 1017
Hexatriacontane, reaction with aluminum chloride, 201, 202
Hexene, detonating properties of, 1017
—, dodecene from, 1299, 1300
—, free energy of formation, 1225, 1226, 1295
—, from ethyl alcohol, 173
—, from ethylene, 258
—, from hexane, 257
—, from *n*-nonane, 72
—, from propene, 75
—, from *n*-tetradecane, 1297
—, hexane from, 1299
—, hydration of, free energy change, 1303
—, hydrogenation of, free energy change, 1299
—, isomerization of, 87, 643
—, polymerization of, free energy change, 1299, 1300
—, reaction with benzene, 591, 598
Hexenes, from carbon monoxide and hydrogen, 1243
—, from propene, 75, 79, 639, 641
—, hexanols from, 388
—, in gasoline, 144
—, polymerization of, 643
—, reaction with formic acid, 312
—, — sulphuric acid, 308, 388, 389

Hexene-1,2-oxide, preparation of, 589
Hexene-1,2-oxide, reaction with hydrobromic acid, 589
Hex-3-enoic acid, reaction with ethyl hypochlorite, 627
Hexone, *see* Methyl isobutyl ketone
Hexylacetylene, preparation of, 722
Hexyl alcohol, *see* Hexanol
2-Hexylamine, from 2-nitrohexane, 1094
Hexyl chloride, formation of, 306
sec-Hexyl esters, plasticizers, cellulose nitrate, 409
sec-Hexyl mercaptan, in petroleum, 454
ter-Hexyl formate, preparation, 312
Hexylresorcinol, stabilizing agent, 328
1-Hexyne, preparation of, 146, 722
—, reaction with ozone, 904
Hillman test, for color stability of kerosene, 925
Horn, reaction with ethylene oxide, 561
Houdry process, of commercial cracking, 125-129
Humic acids, as emulsifying agents, 1099, 1218
Hydration, of acetylene, 712, 713, 714
—, butenes, 293-296
—, divinylacetylene, 709
—, ethylene, 282-291
—, —, free energy change, 1302, 1303
—, 1-hexene, free energy change, 1303
—, isobutene, 294-296
—, —, free energy change, 1303
—, 2-methylbutene-2, 296, 297
—, 2-methylpropene, 296, 297
—, propene, 288, 291, 292, 293
—, vinylacetylene, 705
Hydraulic cement, alkylolamine soaps in, 575
Hydrazine, as antiknock, 1018
—, reaction with aldehydes, 886
—, — ketones, 448
Hydrazobenzene, antioxidant, for gasoline, 917
Hydriodic acid, catalyst, isomerization of cyclohexane, 1302
Hydroabietic acid esters, emulsifying agents for asphalts, 1217
Hydroaromatics, *see* Cycloparaffins
Hydrobiphenyl, from benzene, 95
Hydrobromic acid, effect on hydration of olefins, 410
—, reaction with butadiene, 699
—, — hexene-1,2-oxide, 589
Hydrocarbons, pressure-volume-temperature relations, 1320, 1321
—, reaction with steam, 277, 278, 280
—, — sulphur, 467, 468
Hydrocarbon number, effect, on knock rating, 1027, 1028
Hydrocarbon oils, extraction with sulphur dioxide, 212, 1070
—, oxidation of, 1045, 1061
Hydrocarbon structure, effect, on knock rating, 1024, 1025, 1027, 1028
—, — lead susceptibility, 1033
Hydrochloric acid, acidation with, 9
—, catalyst in condensation of acetone, 431
—, —, cracking, 114
—, —, dehydration of tertiary alcohols, 410
—, —, esterification of isopropyl alcohol, 377
—, —, ethyl alcohol from ether, 333
—, —, ethylene-carbon monoxide reaction, 893
—, —, hydration of olefins, 297, 410
—, for extraction of nitrogen bases, 833
—, from carbon tetrachloride, 731
—, in estimation of ethylene oxide, 556
—, — lead tetraethyl in gasoline, 1165
—, in purification of triethanolamine, 567
—, in refining gasoline, 669
—, reaction with ethylene glycol, 537
—, — monovinylacetylene, 680
—, — olefins, 310, 311
—, — *sec*-nitropropane, 1096
Hydrocyanic acid, from hydrocarbon gas, 851
—, from methane and ammonia, 871
Hydrofined naphthas, in sulphate detergents, 1086
Hydrofluoric acid, effect, on ignition temperatures, 986, 987
—, promoter, mercury catalysts, 717
Hydroformed naphthas, in sulphate detergents, 1086
—, oxidation of, 1054
Hydrogen, antioxidant, for gasoline, 918
—, as motor fuel, 1040
—, by pyrolysis of aromatics, 95, 96
—, — cycloparaffins, 90, 92, 93
—, — ethylene oxide, 554
—, — olefins, 74-76, 79, 81, 83, 85-87, 166
—, — paraffins, 52, 60-65, 68-72, 149-151, 154, 161, 165, 168, 180, 218-229, 234, 269, 1247
—, combustion of, 1003, 1004
—, —, for supplying heat in pyrolysis reactions, 168
—, deasphalting agent, 45
—, diluent, oxidation of ethylene, 552
—, —, pyrolysis of hydrocarbons, 167, 179, 220
—, effect on chlorination of olefins, 492, 493
—, — cracking, 138
—, — electrical decomposition of hydrocarbons, 254
—, — polymerization of acetylene, 703
—, —, — ethylene, 166, 639, 647
—, — pyrolysis of hydrocarbons, 37, 79, 89, 95, 219
—, — thermal decomposition of ethylene oxide, 554
—, — voltolization, 261, 262
—, estimation of, in gases, 1127, 1128
—, formation during cracking, 99, 108, 131, 137, 138, 140, 1297
—, for preparation of cracking catalysts, 112
—, for removal of sulphur compounds, 1248, 1249
—, from carbon dioxide and methane, 273, 274
—, from carbon monoxide and steam, 277
—, from coal, 1246
—, from coke-oven gas, 1246-1248
—, from ethyl alcohol, 339-341, 347, 348, 352
—, from generator gas, 1246
—, from hydrocarbons and steam, 220, 229, 269-280, 1247
—, —, by action of electric arc, 226, 253-255
—, —, by action of silent discharge, 257, 259, 260
—, —, by oxidation, 269, 1246
—, —, by photochemical decomposition, 267
—, from iron and steam, 269
—, from water, 256, 269
—, from water gas, 269, 1247
—, ignition of, 1001
—, ignition temperature of, 987, 988, 997
—, in estimation of olefins, 1145, 1146
—, in estimation, of sulphur, 1157
—, in natural gas, 17, 21
—, in oil cracking, 113, 115
—, in recovery of wax acids, 976
—, inflammability limits of, 982, 983, 985
—, oxidation with copper oxide, 165, 659, 660
—, purification of, 234
—, reaction with acetone, 432
—, — acetyl chloride and ethylene dichloride, 501
—, — acetylene, 171, 719
—, — aldehydes, 885, 889
—, — asphaltenes, 1192
—, — benzene, free energy change, 1298
—, — butadiene, 699
—, — butyl lactate, 546
—, — carbon, 168, 1278
—, — carbon dioxide, 661, 1241, 1242
—, reaction with carbon monoxide, 660, 661
—, —, effect of catalysts on, 1228-1230
—, —, mechanism, 1224, 1225
—, —, thermodynamics, 1225, 1227, 1303-1305
—, reaction with cyclopropane, 761
—, — diisobutylene, free energy change, 1300
—, — divinylacetylene, 709
—, — glycerol, 547
—, — hexene, free energy change, 1299
—, — maleic acid, 945
—, — mercaptans, 1248, 1249
—, — naphthalene, 1154
—, — nitromethane, 1094
—, — olefins, 57, 58, 1145, 1146, 1154, 1245
—, — peanut oil, 1154
—, — petroleum hydrocarbons, 18, 138

Hydrogen, reaction with phthalic anhydride and carbon dioxide, 950
—, — sulphur, 1157
—, — sulphur compounds, 1248, 1249
—, — thiophene, 484, 485
—, — toluene, 347
—, — unsaturates, 1153, 1154
—, removal, by salt solutions, 457
—, —, from cracking gas, 657, 659, 660, 661
—, —, from gas mixtures, 1133
—, —, from olefins, 165
—, to improve carbon black, 248, 249
Hydrogenated cyclic compounds, 688
Hydrogenated oils, as lubricants, 576
—, autoxidation inhibitors for, 914
Hydrogenated safety fuel, ignition of, 1002
Hydrogenated tar, voltolization of, 262
Hydrogen bromide, catalyst, bromination of ethylene, 503
—, —, halogenation of cyclopropane, 761
—, reaction with allyl acetic acid, 318
—, — butadiene, 686
—, — methylacetylene, 723
—, — olefins, 298, 307, 315-318
—, — styrene, 318
—, — vinyl halides, 315, 716
Hydrogen chloride, catalyst, chlorination of cyclohexane, 766
—, —, — ethylene dichloride, 501, 742
—, —, condensation of polyhydric alcohols, 579
—, —, hydration of ethylene, 288
—, —, isomerization of cyclohexane, 1302
—, —, polymerization of aldehydes, 579
—, —, — olefins, 665
—, —, pyrolysis of hydrocarbons, 158, 168
—, —, reaction of aldehydes and cracked distillates, 625
—, —, — glycols and formaldehyde, 543
—, —, — hydrocarbons and aluminum chloride, 199-201, 203, 204, 207, 215
—, —, — olefins and carbon monoxide, 446, 625
—, —, — polyglycols and arsenious oxide, 545
—, diluent, chlorination of methane, 726
—, effect, on ignition temperature of hydrogen, 998
—, electrolysis of, 780
—, estimation of, in gases, 1127
—, in preparation of aluminum chloride catalyst, 196, 204, 214
—, reaction with acetone, 429
—, — acetylene, 716
—, — benzene, 950
—, — diethyl sulphate, 327
—, — diolefins, 686
—, — ether, 345
—, — ethyl alcohol, 345, 742
—, — ethylene glycol, 537
—, — ethylene oxide, 560
—, — gasoline, 928
—, — monovinylacetylene, 680, 706
—, — olefins, 204, 302, 303, 306, 310, 311
—, — 1-(2'-phenyl) ethylcyclohexene-1 and ethyl nitrite, 619
—, — vinyl esters, 716
— to remove iron from acetylene black, 244
Hydrogen chloride molybdic anhydride complex, reaction with ethylene, 628
Hydrogen content, characterization factor from, 1309
Hydrogen cyanide, from methane and ammonia, 280, 281
—, from nitric oxide and methane, 281
—, reaction with aldehydes, 886
—, — ketones, 448, 451
Hydrogen fluoride, diluent, fluorination of benzene, 792
—, extraction agent, 1108, 1109
—, fluorinating agent, 735
—, from fluoroform, 737
—, reaction with acetylene, 716
—, — carbon disulphide and chlorine, 737
—, — dichloroethane, 747
—, — olefins, 307
—, — unsaturated acids, 307
Hydrogen halides, catalysts, reaction of carbon monoxide and methanol, 1050
—, —, reaction of carbon monoxide and olefins, 625, 626
—, reaction with acetylene, 716
Hydrogen iodide catalyst, formation of biphenyl, 191
—, reaction with isopropyl hydroperoxide, 382
—, — propene, 316, 317
—, — vinyl chloride, 716
Hydrogen-nitrogen mixture, preparation of, 277
Hydrogen peroxide, effect on pentene-sulphuric acid reaction, 318
—, in estimation, of sulphur, 1125, 1161, 1162
—, reaction with acetone, 432
—, — aliphatic acids, 852
—, — cyclohexene, 852
—, — diisopropyl sulphate, 381
—, — ethylene, 897
—, — formaldehyde, 887
—, — hexadecene-1, 548
—, — lead mercaptides, 475
—, — olefins, 547, 895
—, — trimethylethylene, 547
—, refining agent, lignite spirits, 928
—, stability in tertiary butyl alcohol, 895
—, sweetening agent, 478, 490
Hydrogen polysulphide, reaction with divinylacetylene, 709
Hydrogen sulphide, action of electrical discharge on, 463
—, adsorption by charcoal, 461
—, catalyst, formation of *ter*-butyl acetate, 412
—, corrosion by, 456
—, detection of, 466, 1259
—, effect on carbon black yield, 237
—, — deposition of carbon, 192
—, — Kogasin synthesis, 1236
—, estimation of, 1125
—, from mercaptans, 478
—, ignition temperature of, 987
—, in natural gas, 22, 1121
—, in petroleum, 454
—, oxidation of, 460, 461
—, properties of, 461, 462
—, reaction with acetylene, 720
—, — di-*ter*-butyl sulphate, 463
—, — ethylene oxide, 463
—, — formaldehyde, 463
—, — furan, 463
—, — halogens, 464
—, — isoprene, 463
—, — olefins, 462, 463
—, — phosphoric acid, 466
—, — rosin, 466
—, recovery from spent alkali, 458
—, removal of, 23, 165, 170, 398, 457-460, 573-575, 1249
—, solubility, 461, 462
—, sulphuric acid from, 464
Hydrolysis, of *ter*-amyl acid sulphate, 394
—, *ter*-amyl bromide, 803
—, amyl chloride, 801-803
—, *sec*-amyl sulphate, 395
—, *ter*-butyl acid sulphate, 394
—, butyl halides, 797-800
—, carbyl sulphate, 1081
—, chlorobenzene, 782, 783, 784
—, chlorotoluene, 794
—, of cyanohydrins, 886
—, dibromocyclobutane, 762, 763
—, dibromocyclopropane, 762
—, *o*-dichlorobenzene, 785
—, 1,2-dichloro-2-methylpropane, 797
—, dihaloethanes, 532
—, disodium naphthalene, 958
—, ethyl chloride, 796, 797
—, ethylene chlorohydrin, 518, 519, 533
—, ethylene dichloride, 533, 797
—, ethylsulphuric acid, 319, 325, 326
—, fats, 1069
—, isobutyl bromide, 799
—, isobutyl chloride, 798
—, isopropyl chloride, 797

Hydrolysis, isopropyl hydrogen sulphate, 325
—, lead mercaptides, 471
—, methyl chloride, 727, 728, 796
—, methylene chloride, 728
—, polypropene sulphone, 618
—, sulphonic acids, 1067, 1068, 1081
—, 1,2,3-trichloro-3-methylpropane, 797, 798
Hydrolyzing agents, sulphonic acids as, 1069
Hydrophilic lipins, preparation of, 545
—, utilization of, 545, 546
Hydroquinone, as antioxidant, 337, 855, 907, 913, 914, 917
—, effect on color stability, 926
—, from benzene, 942
—, from benzoquinone, 953
—, inhibitor, ketone cyanohydrin polymerization, 451
—, promoter, oxidation of oils, 1044
—, quinone from, 1277
—, reaction with isopropyl hydroperoxide, 382
Hydroquinone dianilide, as antioxidant, 918
—, effect on color stability, 926
Hydroquinone phenyl ether, as heat-transfer medium, 861
Hydrorubber, motor fuel from, 1040
Hydrothiophenes, *see* Thiophanes
p-Hydroxyacetonitrile, as antioxidant, 915
Hydroxy acids, dehydration of, 968
—, effect on color stability, 937
—, from bromo acids, 447
—, from ceresins, 975
—, from lubricating oil, 855
—, from paraffin wax, 971
—, from petroleum, 963
—, reaction with ketene, 438
Hydroxyaldehyde, from ethylene glycol, 536
Hydroxyalkylamine esters, effect on color stability, 927
Hydroxyalkylamines, preparation of, 570
—, reaction with carbonic acid, 569
Hydroxyalkylcellulose, preparation of, 559
Hydroxyaryl ethers, as antioxidants, 938
Hydroxyazobenzene, as antioxidant, 917
Hydroxyazo compounds, condensation with cyclopentadiene, 692, 693
Hydroxybiphenyl, *see* Phenylphenol
Hydroxychrysenes, as antioxidants, 918
2-Hydroxycyclohexylcarbinol, from cyclohexene, 624
3-Hydroxy-3,4-di*ter*-butyl-1-butene, reaction with oxalic acid, 679
Hydroxyethylamine, from ethylene oxide, 560
β-Hydroxyethylarsenous acid, preparation of, 527
β-Hydroxyethylarsonic acid, preparation of, 527
Hydroxyethyl ethers, utilization of, 558
Hydroxyethyllignin, preparation of, 559
1-Hydroxyethyl-5-naphthol, preparation of, 569
1-*β*-Hydroxyethylpyridoneimine, preparation of, 561
β-Hydroxyethyl sulphonate, preparation of, 565
Hydroxyethyl thioethers, preparation of, 564
2-Hydroxy-3-isopropylbenzoic acid, formation of, 308
Hydroxyketo acids, preparation of, 843, 1053
Hydroxyketone, preparation of, 536
Hydroxylamine, from nitrolic acids, 1094
—, reaction with aldehydes, 886
—, — ketones, 448
Hydroxylamine esters, as wetting agents, 576
Hydroxylation, of olefins, 532, 534, 535, 547, 895, 897
—, of paraffins, 844-846
Hydroxymanganese acetate, catalyst, acids from alcohols, 1050
o-Hydroxymesitylenic acid, from mesitylene, 954
4-Hydroxy-4-methyl-2-hexanone, preparation of, 433
5-Hydroxy-5-methyl-3-hexanone, preparation of, 433
Hydroxymethylhydroperoxide, preparation of, 887
Hydroxyphenanthrenes, as antioxidants, 918
Hydroxyphenylazo-*α*-naphthol, as antioxidant, 916
Hydroxyphenylglycine, as antioxidant, 915
Hydroxypicenes, as antioxidants, 918
α-Hydroxypropionic acid, *see* Lactic acid
Hydroxypropylamines, preparation of, 585
Hydroxystearosulphuric acid, catalyst, sulphation of propene, 358
Hydroxysulphones, from butadiene sulphone, 695, 696
Hydroxytetrahydroquinoline, as antioxidants, 918
Hydroxy thioethers, reaction with thionyl chloride, 526
Hymolal, definition of, 1082
Hypochlorites, desulphurizing agents, 490
—, sweetening agents, 475, 478
Hypochlorous acid, desulphurizing agent, 115, 490
—, reaction with 2-butene, 509, 547, 548
Hypochlorous esters, reaction with olefinic acids, 627
Hypohalites, catalyst, oxidation of oils, 1054
Hypohalites, reaction with vinylacetylene, 706

I

Ichthyols, definition of, 1080
Icterus index, definition of, 1261
Igepons, detergent properties of, 1082, 1084
—, structure of, 1082, 1084
Ignition, by compression, 1000, 1001
—, by electrical discharge, 1001, 1002, 1009, 1010
—, by heated surfaces, 986, 987
—, effect on octane number, 1030
Ignition temperature, determination of, 987, 988
—, effect of antiknock compounds, 996
—, — catalysts, 1000, 1001
—, — concentration, 989-992
—, — hydrocarbon structure, 998, 999
—, — knock-inducing compounds, 996
—, — metal oxides, 1000
—, — pressure, 992-996
—, — water vapor, 996, 997
—, of acetylene, 988
—, ammonia, 987
—, benzene, 987, 988, 1000
—, butane, 992
—, carbon black, 245
—, carbon disulphide, 987
—, carbon monoxide, 987, 988, 997
—, cyanogen, 987
—, diethyl ether, 987-989
—, ethane, 987-989, 992, 993
—, ethylene, 987-989
—, gasoline, 990, 991, 995, 996, 998
—, hexane, 992
—, hydrogen, 987, 988, 997
—, hydrogen sulphide, 987
—, isobutane, 992
—, isooctane, 991, 992
—, methane, 986-988, 992, 993, 995-997
—, octane, 991
—, pentane, 987, 988, 992, 995, 1000
—, propane, 988, 989, 992, 993
—, propene, 988
Ignition-temperature depressants, nitro compounds as, 1097
Illuminating gas, from Gasol, 1255
—, from polymerization gases, 674
Imides, as antioxidants, 915
Impregnating agents, from halogenated wax, 759
Indanes, preparation of, 649
Indene, chlorohydrin from, 626
—, from cracking gas, 645, 646
—, from dicyclopentadiene, 156
—, from natural gas, 155, 183
—, from propene and benzene, 156, 645
—, from toluene and ethylene, 156, 645, 646
—, resins from, 155
Indoles, extractants for asphalts, 1202
Indophenol, as antioxidant, 913
Inflammability limits, definition of, 980
—, effect of flame propagation, 982, 983
—, — inert gases, 983-986
—, — pressure, 980
—, — temperature, 980-982
Infra-red rays, absorption by hydrocarbons, 32
Insecticides, acetaldehyde in, 891
—, alcohols in, 790, 1059, 1078
—, aluminum sulphate in, 1112
—, benzene in, 733
—, calcium caseinate in, 1112

Insecticides, carbon tetrachloride in, 732, 733
—, casein in, 1077
—, castor oil in, 1077
—, chlorobenzenes in, 782, 790
—, chloroethanes in, 745
—, derris in, 1078
—, disulphides in, 1112
—, efficiency of, 1058-1060
—, fatty acid soaps in, 1077
—, glyceryl oleate in, 1115
—, green acids in, 1077
—, Kontakt as, 1077
—, lead tetraalkyls in, 823
—, mahogany acids in, 1077
—, mercaptans in, 487, 1112
—, naphthenates in, 1112, 1114, 1115
—, naphthenic acids in, 487, 1112, 1113
—, β-naphthol in, 790
—, nicotine sulphate in, 1077, 1078
—, Penetrol in, 1078
—, petroleum distillates in, 545, 790, 978, 1058, 1059, 1077, 1078, 1112, 1115
—, phenols in, 487, 1112, 1113
—, polyglycol arsenites in, 545
—, pyrethrum in, 1078
—, rhodanates as, 1059
—, rosin in, 790
—, sulphonic acids as, 487, 1077, 1078
—, sulphonates in, 1077, 1078
—, sulphur in, 1114
—, sulphur dioxide in, 1077
—, wax acids in, 978
Insulating oil, carbon black in, 251
—, oxidation of, 930, 939
—, preparation of, 937
Intensive property, definition of, 1272
Internal energy, relation to heat content, 1273, 1274
Iodine, adsorption with carbon black, 249, 252
—, catalyst, aquolization, 132
—, —, bromination of benzene, 790, 791
—, —, — toluene, 795
—, —, condensation of ethylene glycol, 544
—, —, cracking, 114

—, — methylene radicals, 51
—, — sodium acetylide, 711
—, — sulphur dioxide, 1125
—, — unsaturates, 491, 1125
Iodine chloride, catalyst, chlorination of ethylene, 495
—, —, chlorination of propene, 507
Iodine halides, reaction with unsaturates, 1152
Iodine number, of gasoline, 1045
Iodine pentoxide, reaction with carbon monoxide, 1128
Iodoalkyl nitrates, preparation of, 629
Iodobenzene, amines from, 787
—, reaction with potassium amide, 787
Iododifluoromethane, preparation of, 737
Iodoform, di-iodofluoromethane from, 737
—, fluoroform from, 737
—, from acetone, 430
—, iododifluoromethane from, 737
—, structure of, 729
2 Iodopentane, preparation of, 763
Iodosilver benzoate, reaction with acetylene, 711
—, — butadiene, 697
Iron, catalyst, acetone from acetaldehyde, 423
—, —, bromination of ethane, 747
—, —, — benzene, 790, 791
—, —, carbon from carbon monoxide, 229
—, —, chlorination of acetylene, 743
Iron, catalyst, chlorination of benzene, 778, 779
—, —, — carbon disulphide, 730
—, —, — difluoromethane, 734, 735
—, —, — ethane, 741
—, —, — olefins, 493
—, —, — toluene, 793
—, —, combustion of natural gas, 225
—, —, cracking, 112, 114
—, —, fluorination of benzene, 791
—, —, halogenation of dibromocyclobutane, 763
—, —, — of naphthenes, 760
—, —, — petroleum distillates, 490
—, —, hydration of ethylene, 291
—, —, oleone from oleic acid, 446
—, —, oxidation of ethylene, 552, 553, 893
—, —, — kerosene, 965
—, —, — lubricants, 932
—, —, — methane, 869
—, —, — naphthenes, 940
—, —, polymerization of acetylene, 704
—, —, — pinene, 645
—, —, pyrolysis of aliphatics, 153, 180, 189, 218
—, —, — olefins, 76, 77, 79, 172
—, —, — pinene, 88
—, —, reaction of acetyl chloride and ethylene dichloride, 501
—, —, — carbon and hydrogen, 1278
—, —, — hydrogen bromide and allyl bromide, 315
—, —, — methane and steam, 272
—, —, reduction of carbon dioxide, 1242
—, —, — carbon monoxide, 1223-1225, 1228, 1229, 1231, 1233, 1241, 1249
—, —, — nitroethane, 1094
—, —, sulphation of ethylene, 323
—, effect on decomposition of carbon tetrachloride, 730
—, reaction with sulphur, 1157
—, — trichloroethylene, 711
—, refining agent for gasoline, 668
—, stabilizer, for ether, 335, 337
Iron acetate, catalyst, hydration of acetylene, 714
Iron acetylacetonates, catalysts, phenylcyclopentane autoxidation, 907
Iron alloys, inhibitors, decomposition of ethylene oxide, 554
Iron antimonide, catalyst, dehydrogenation of *sec*-alcohols, 419
Iron arc, action on acetylene, 264
Iron arsenide, catalyst, dehydrogenation of *sec*-alcohols, 419
Iron bismuthate, catalyst, dehydrogenation of *sec*-alcohols, 419
Iron boro-phosphate, catalyst, hydration of ethylene, 285
—, —, — propene, 292
Iron carbonate, catalyst, methane-steam reaction, 278
Iron carbonyl, as antiknock, 1017, 1018
—, catalyst, reaction of phthalic anhydride and carbon monoxide, 950
—, effect on inflammability limits, 985
—, reaction with tetralin peroxide, 906
Iron chloride, catalyst, alkylation of alcohols, 606
—, —, cracking, 112
—, —, ethylation of amines, 347
—, —, polymerization of olefins, 203, 204, 636, 665
—, —, reaction of paraffins and nitrosyl chloride, 1102
—, desulphurizing agent, 488
—, refining agent for petroleum, 719, 928
Iron compounds, catalyst, chlorination of acetylene-hydrogen mixtures, 710
—, —, ethylene-sulphuric acid reaction, 323
—, effect on color stability, 938
—, *see also* Ferric and Ferrous compounds
Iron cyanide, catalyst, sulphation of isobutene, 391
—, —, — propene, 358
Iron fluoride, catalyst, reaction of propene and hydrogen fluoride, 307

Iron halides, catalyst, cracking, 198
—, —, hydration of acetylene, 712
—, —, pyrolysis of hydrocarbons, 158
—, —, reaction of olefins and carbon monoxide, 625
Iron hydroxide, catalyst, reaction of methane and steam, 278
—, —, — sulphur and hydrocarbons, 467
—, for sulphur removal, 459, 1249
Iron iodide, catalyst, reaction of acetone and phenylnaphthylamine, 429
Iron naphthenate, as wetting agent, 1117
Iron ore, for hydrogen sulphide removal, 460
Iron oxide, catalyst, acetone formation, 423
—, —, cracking, 128, 137
—, —, decarboxylation of phthalic anhydride, 951
—, —, dehydration of alcohols, 331
—, —, dehydrogenation of alcohol, 337
—, —, dipropyl ketone from *n*-butyl alcohol, 443
—, —, ethyl alcohol from ether, 334
—, —, ethylation of amines, 347
—, —, hydration of acetylene, 714
—, —, — ethylene, 291
—, —, oxidation of aromatics, 942, 945, 950
—, —, — of ethyl alcohol, 423
—, —, — hydrogen sulphide, 460
—, —, — methyl alcohol, 878
—, —, polymerization of acetylene, 704
—, —, — butadiene, 674
—, —, — olefins, 665
—, —, reaction of ethyl alcohol and steam, 421, 422
—, —, — methane and steam, 278
—, —, — phthalic anhydride and carbon monoxide, 950
—, —, — sulphur and hydrocarbons, 467
—, —, reduction of carbon monoxide, 1229, 1231
—, desulphurizing agent, 23, 1248, 1249
—, effect on ignition temperature, 1000
—, magnetic, catalyst, pyrolysis of hydrocarbons, 157, 192
Iron phosphate, catalyst, hydration of ethylene, 287
—, —, —, propene, 292
—, —, reaction of ethers and alkyl halides, 345
Iron phosphide, catalyst, dehydrogenation of *sec*-alcohols, 419
Iron salts, catalysts, acids from alcohols, 1051
—, —, oxidation of hydrogen sulphide, 461
—, —, — toluene, 950
—, —, polymerization of olefins, 929
—, —, sulphation of isoolefins, 308
Iron selenide, catalyst, dehydrogenation of *sec*-alcohols, 419
Iron sulphate, catalyst, ethylation of amines, 347
—, —, sulphation of propene, 358
Iron sulphide, desulphurizing agent, 397
Iron telluride, catalyst, dehydrogenation of *sec*-alcohols, 419
Iron vanadate, catalyst, oxidation of anthracene, 952
Isethionic acid, condensation with oleic acid, 1082
—, from carbyl sulphate, 1081
Isoacids, from isoaldehydes, 889
Isoaldehydes, oxidation of, 889
Isoamyl alcohol, as antiknock, 1017
—, in motor fuel, 1035
—, octane number of, 1028
Isoamylbenzene, from sapropelite tar, 144
Isoamyl bromide, from amylene, 513
Isoamyl chloride, reaction with anthracene, 827
—, — magnesium, 823
Isoamylcyclopentane, pyrolysis of, 91
Isoamylene, from amine nitrates, 623
—, from dimethylaniline, 623
—, reaction with sulphuric acid, 412
—, — thymol, 606
—, *see also* Isopropylethylene, 2-Methyl-2-butene and Trimethylethylene
Isobar, definition of, 1307
Isobutane, acetylene from, 66, 67, 166
—, chlorination of, 752
—, ethylene from, 67
—, from *n*-butane, 201
—, —, entropy change, 1282
Isobutane, from *n*-butane, free energy change, 1282
—, —, heat of reaction, 1282

—, from ethylene, 637
—, from *n*-hexane, 201
—, from natural gas, 22
—, heat of combustion, 15
—, ignition temperature of, 992
—, inhibitor, decomposition of ethylene oxide, 554
—, in petroleum, 21
—, isobutene from, 66
—, isooctane from, 1301
—, nitration of, 1088
—, propene from, 66
—, pyrolysis of, 65-67, 148, 555
—, reaction with cyclopropane, 602
—, — ethylene, 599, 601
—, — isobutene, 599
—, — isobutene, free energy change, 1301
Isobutene, acetylene from, 84
—, anthracene from, 85
—, benzene from, 85
—, butadiene from, 85, 86
—, *ter*-butyl alcohol from, 386, 390, 391
—, —, free energy change, 1303
—, *ter*-butyl mercaptan from, 463
—, *ter*-butylsulphuric acid from, 308
—, diisobutylene from, 386, 1300
—, effect on polymerization of *n*-butene, 642
—, ethylene from, 85
—, free energy of formation, 1284
—, from cyclohexane, 92
—, from gas oil, 140
—, from isobutane, 66
—, from isopentane, 69
—, from 2-isopropyl-3,3-dimethyl-1-butene, 411
—, from methylcyclopentane, 90
—, from neopentane, 69
—, from tetramethylpentanol, 401
—, hydration of, 294-297
—, —, free energy change, 296, 1303
—, —, heat of activation, 295
—, isobutenediamine from, 619
—, isobutene glycol from, 895
—, isooctane from, 1300, 1301
—, molal entropy, 1291
—, naphthalene from, 85
—, nitration of, 622
—, oils from, 85, 210
—, oxidation of, 622
—, polymerization of, 210, 296, 390, 633, 641-643
—, —, free energy change, 1300
—, propane from, 84
—, propene from, 85
—, pyrolysis of, 84, 85, 184
—, reaction with benzene, 591, 594, 596
—, — *ter*-butyl hypochlorite, 518
—, — chlorine, 508
—, — 1,3-dimethoxybenzene, 606
—, — ethylene glycol, 544
—, —, hydrogen bromide, 317
—, reaction with isobutane, 599
—, —, free energy change, 1301
—, reaction with isopropyl alcohol, 607
—, — methoxy toluene, 605, 606
—, — sulphur dioxide, 618
—, — sulphuric acid, 308, 385, 386, 391, 1142
—, separation from *n*-butene and butadiene, 386
—, toluene from, 85
—, triethylethylene from, 85
—, triisobutylene from, 591
Isobutene chloride, chlorobutenes from, 508
—, hydrolysis of, 798
Isobutene chlorohydrin, from isobutene, 518, 520
Isobutenediamine, from isobutene, 619
Isobutene glycol, from isobutene, 547, 895
Isobutene nitrosite, preparation of, 620
Isobutene oxide, in adhesives, 586
—, reaction with alcohols, 548, 589
—, — dibenzylamine, 589
Isobutene polymers, motor fuel from, 1040
—, uses of, 674, 675

Isobutyl alcohol, as antiknock, 1017, 1018
—, in motor fuels, 375
—, octane number of, 1028
—, reaction with phenol, 403
—, — ricinoleic acid, 1086
Isobutylbenzene, from sapropelite tar, 144
Isobutyl bromide, dimethylethylene from, 806
—, hydrolysis of, 799
Isobutyl chloride, reaction with phenanthrene, 827
Isobutyraldehyde polymers, motor fuel from, 1040
Isobutyric acid, from isopropylethylene glycol, 548
—, from propene, 626
Isochore, definition of, 1307
Isochloroprene, preparation of, 707
Isohexane, detonation of, 1017
—, from carbon monoxide and hydrogen, 1243
—, from *n*-hexane, 199
Isohexanol, reaction with phenol, 403
Isomerization, of butenes, 81, 82, 642
—, of cyclohexane, free energy change, 1301, 1302
—, of cyclopropane, 90
—, of cyclopropene, 88
—, of *n*-hexane, 200
—, of *n*-hexene, 87, 643
—, of methylacetylene, 88
—, of methylallene, 88
—, of pentenes, 86
Isomorphism, definition of, 422
Isonitroparaffins, preparation of, 1092
Isonitrosoethyl methyl ketone, preparation of, 452
Isononane, in petroleum, 33
Isooctane, as antioxidant, 875
—, as motor fuel, 97
—, from isobutane, 1301
—, from isobutene, 1300, 1301
—, from *n*-octane, 199
—, from petroleum, 32
—, ignition temperature of, 991, 992
—, reference standard in knock rating, 141, 1025-1027
Isooctenyl aldehyde, from butyraldehyde, 878
Isooctylhydrindene, naphthalene from, 94
Isoolefins, as antiknocks, 417
—, polymerization of, 204
—, reaction with sulphuric acid, 308
Isoparaffins, free energy of formation, 1281, 1282
—, in brown coal paraffins, 38
—, in petroleum, 31, 32
—, molal entropy, 1281, 1282, 1289
—, —, effect of structure on, 1288, 1289
—, uses of, 674
Isopentadecane, chlorination of, 1253
Isopentane, diisoamyl ketone from, 445
—, from carbon monoxide and hydrogen, 1243
—, from ethylene and propane, 601
—, from *n*-pentane, 201, 445
—, from petroleum, 21
—, inflammability limits of, 980, 981

Lead alkyls, as antiknock agents, 829, 1018
—, preparation of, 255, 256, 1102
Lead borate, catalyst, pyrolysis of paraffins, 160
Lead chloride, catalyst, iodination of cyclohexene, 774
—, —, polymerization of olefins, 665
Lead chromate, catalyst, hydrogenation of sulphur compounds, 1248, 1249
—, —, oxidation of toluene, 948
Lead compounds, catalyst, pyrolysis of pinene, 905
—, effect on ignition temperature of oils, 938
Lead derivatives, catalysts, oxidation of toluene, 947
Lead dimethyl, as antiknock, 1018
Lead dimethyldiamyl, as antiknock, 1018
Lead dioxide, catalyst, oxidation of methane, 867
—, —, — petroleum oils, 1050
—, for color stability of kerosene, 925
Lead fluoride, use in fluorination, 734, 737
Lead halides, catalyst, dehydrogenation of hydrocarbons, 158
—, —, reaction of olefins and carbon monoxide, 625, 626
Lead mahogany sulphonate, in lubricants, 1079
Lead mercaptides, hydrolysis of, 471
—, preparation of, 471
—, reaction with hydrogen peroxide, 475
—, — potassium permanganate, 475
Lead molybdate, catalyst, oxidation of toluene, 948
Lead naphthenate, as antioxidant, 937
—, as drying agent, 1115
—, as wetting agent, 1117
—, in lubricants, 1116
—, in paints, 1115
Lead nitrate, effect on naphthenic acid salts, 1115
Lead oleate, catalyst, oxidation of pinene, 905
Lead oxide, catalyst, decarboxylation of phthalic anhydride, 950, 951
—, —, esterification of pentaerythritol, 1055
—, —, oxidation of aromatics, 942
—, —, — olefins, 553
—, effect on ignition temperature, 1000
—, from lead sulphide, 476
—, from spent doctor solution, 476
—, reaction with *β*,*β*-dichlorodiethyl ether, 579
—, — trimethylene bromide, 547
—, sweetening agent, 476
Lead phosphate, catalyst, hydration of ethylene, 287
Lead sodium alloy, use in gasoline chlorination, 755

Lead sucrate, antioxidant, 917
Lead sulphate, catalyst, ethylene-sulphuric acid reaction, 323
—, —, propene-phosphoric acid reaction, 358
—, —, propene-sulphuric acid reaction, 358
—, promoter, hydration of propene, 292
Lead sulphide, lead oxide from, 476
—, sweetening agent, 475, 476
—, use in refining oils, 1044
Lead susceptibility, definition of, 1031
—, effect of disulphides, 480, 481, 1031
—, — hydrocarbon structure, 1032
—, — thioethers, 1031
Lead tetra-alkyls, reaction with phenol, 823
Lead tetraethyl, as antiknock, 1013, 1017-1022, 1251
—, catalyst, oxidation of naphtha, 876
—, effect, on acetylene homologues, 1019-1021
—, — aromatics, 1019, 1021, 1022
—, — cyclohexane, 1022

—, — oxidation of benzene, 944
—, — oxidation of gasoline, 861, 947
—, — paraffins, 1019
—, estimation in gasoline, 1165, 1166
—, preparation of, 823
—, reaction with phenol, 823
—, reducing hazards of, 829
—, thermal decomposition of, 1022, 1023
Lead tetramethyl, photolysis of, 1022
Lead tetraphenyl, decomposition of, 1022
—, photolysis of, 1022
Lead tungstate, catalyst, oxidation of toluene, 948
Lead vanadate, catalyst, oxidation of toluene, 948
Leather solvents, preparation of, 825
Le Chatelier's principle, application of, 101
Lecithin, from soy beans, 728
—, from corn, 728
Lepidine, from cottonseed meal, 840
Leucocytosis, effect of cyclopropane, 1268
Leucoindophenol, gum inhibitor, 913
Lewis process, for carbon black, 240
Light, effect on carbene precipitation, 1193
—, — chlorination of methane, 726
—, — gasoline, 924
—, — paraffin-nitrosyl chloride reaction, 1101
Lignin, reaction with ethylene oxide, 559
—, source of petroleum, 19
Lignite, adsorbent carbon from, 227
—, chlorination of, 227
—, inhibitor of gum formation, 914
—, motor fuel from, 136
—, use in cracking, 111
Lignite spirits, refining of, 928
Lime, dehydrating agent, 328, 330
—, catalyst, pyrolysis of oxygenated hydrocarbons, 340
—, use in purification of acetylene, 170
Limonene, reaction with formaldehyde, 624
Liquefaction, of ketene, 441
—, of olefins, 161
Liquid air, determination of acetylene in, 702
Lithia, catalyst, pyrolysis of oxygenated hydrocarbons, 340
Lithium alkyls, as antiknocks, 1018
Lithium aryls, as antiknocks, 1018
Lithium chloride, reaction with triethanolamine, 572
Lithium oleate, catalyst, oxidation of petroleum, 964
Lithium sulphate, promoter, hydration of ethylene, 283
Liver, effect of chloroform on, 1262
—, effect of ethylene on, 1262
Loading value, definition of, 221
Locke's solution, definition of, 1269
Long residium, definition of, 37
Lubricants, aluminum naphthenate in, 1116
—, amylene dichloride in, 513
—, asphalt emulsions in, 1220
Lubricants, antioxidants for, 933, 937, 938
—, artificial aging of, 930
—, by polymerization of olefins, 212-215
—, calcium soaps in, 1079
—, decreasing oiliness of, 935

—, solvent extraction of, 41-45
—, sulphonaphthenic acid salts in, 1118
—, use in demulsifying agents, 1116
—, — insecticides, 1078
—, wax acids in, 978, 979

M

Machine oil, resins from, 1188
Magnesia, catalyst, higher alcohols from ethyl alcohol, 339, 340
—, —, pyrolysis of indenes, 95
Magnesite, catalyst, pyrolysis of olefins, 189
—, —, reduction of carbon monoxide, 1241
Magnesium, catalyst, reaction of acetone and ethyl alcohol, 443
—, promoter, reduction of carbon monoxide, 1228-1230, 1242
—, reaction with 9-bromo-phenanthrene, 824
—, — butyl chloride, 823
—, — chlorinated gasoline, 755
—, — ethylene dibromide, 505, 824
—, — isoamyl chloride, 823
Magnesium alkyl halides, preparation of, 822-824

Magnesium alkylsulphonates, surface tension of, 1066, 1067
Magnesium amalgam, catalyst, condensation of acetone, 427
Magnesium antimonide, catalyst, dehydrogenation of *sec*-alcohols, 419
Magnesium arsenide, catalyst, dehydrogenation of *sec*-alcohols, 419
Magnesium bismuthate, catalyst, dehydrogenation of *sec*-alcohols, 419
Magnesium boro-phosphate, catalyst, hydration of ethylene, 285
—, —, — propene, 292
Magnesium bromide, absorption of ethylene oxide with, 557
—, solubility in isopropyl alcohol, 370
Magnesium bromide dietherate, preparation of, 505
Magnesium carbonate, catalyst, ketones from ethyl acetate, 423
Magnesium chlorate, catalyst, reaction of cellulose phthalate and propene oxide, 588
Magnesium chloride, absorption of hydrocarbons by, 1123
—, catalyst, hydrolysis of chlorobenzene, 783
—, —, in cracking, 112
—, reaction with ethylene oxide, 560
Magnesium dimethyl, reaction with cyclohexene oxide, 589
Magnesium halides, catalysts, hydration of acetylene, 712
Magnesium hydroxide, catalyst, reaction of ethylene dichloride and sodium sulphides, 499
—, for hydrogen sulphide removal, 457
—, sweetening agent, 475, 477
Magnesium iodide, solubility in isopropyl alcohol, 370
Magnesium naphthenate, catalyst, oxidation of paraffin wax, 971
—, —, — petroleum, 972
—, in inks, 1117
Magnesium nitrate, catalyst, methane-steam reaction, 278
Magnesium nitride, desulphurizing agent, 490
Magnesium oxide, absorption of saponifiable hydrocarbons by, 732
—, catalyst, acetone from ether, 421
—, —, chlorination of propene dichloride, 507
—, —, dehydrogenation of acenaphthene, 955
—, —, dipropyl ketone from *n*-butanol, 443
—, —, ethyl alcohol from ether, 334
—, —, ethylene oxide from ethylene chlorohydrin, 550
—, —, hydrolysis of chlorobenene, 782
—, —, in cracking, 128
—, —, oxidation of aromatics, 942
—, —, polymerization of butadiene, 674
—, —, pyrolysis of 2-butene, 172
—, —, — thiophene, 483
—, —, reaction of methanol and carbon monoxide, 1050
—, —, — methane and steam, 270, 279
—, —, reduction of carbon monoxide, 661
—, effect on ignition temperature, 1000
—, — inflammability limits, 985
Magnesium phosphate, catalyst, hydration of propene, 292
Magnesium phosphide, catalyst, dehydrogenation of *sec*-alcohols, 419
Magnesium pyrophosphate, catalyst, propionaldehyde from propene oxide, 586
Magnesium salt, catalyst, acids from alcohols, 1051
—, —, ethylene oxide from ethylene chlorohydrin, 550
Magnesium selenide, catalyst, dehydrogenation of *sec*-alcohols, 419
Magnesium silicate, catalyst, pyrolysis of benzene, 192
—, emulsifying agent for asphalt, 1220
Magnesium sulphate, catalyst fermentation of sucrose, 547
—, promoter, hydration of ethylene, 283
Magnesium telluride, catalyst, dehydrogenation of *sec*-alcohols, 419
Mahogany acids, as demulsifying agents, 1075
—, as emulsifying agents, 1074
—, extraction with β,β'-dichloroethyl ether, 530
—, in insecticides, 1077
—, solubility of, 1065
Mahogany soaps, in cleaning compositions, 732
Mahogany sodium sulphonate, in cleaning agents, 746
Mahogany sulphonates, extraction with green-acid soap, 1071, 1072
—, — isopropyl alcohol, 1071
—, — propane, 1071
—, utilization of, 1077-1080
Maleic acid, condensation with diolefins, 945
—, from acenaphthene, 946
—, from benzene, 944
—, from cyclohexanone, 451
—, from furfuraldehyde, 945
—, from naphthalene, 946, 951
—, hydration of, 945
—, reduction of, 945
—, *meso*-tartaric acid from, 547
Maleic anhydride, as antioxidant, 941
—, from benzene, 944-946
—, from fluorene, 954, 955
—, reaction with benzol, 690
—, — diolefins, 175, 679, 698, 699, 1147
—, — olefins, 629
Malic acid, from maleic acid, 945
Malonic acid, preparation of, 904
Maltenes, in asphalt, 1197, 1198
Mandelic acid, acetylation of, 439
Manganese, catalyst, acetone from acetaldehyde, 423
—, —, dipropyl ketone from *n*-butanol, 443
—, —, ethers from acetals, 715
—, —, in cracking, 114
—, —, oxidation of ethylene, 553
—, —, — wax, 971, 1057
—, —, pyrolysis of aliphatics, 189
—, —, reaction of carbon disulphide and chlorine, 730
—, —, — methane and steam, 272
—, promoter, chlorination of benzene, 779
—, —, in cracking, 128
—, —, reduction of carbon monoxide, 1228, 1229, 1231, 1234-1236, 1239, 1240, 1243, 1248
Manganese acetate, catalyst, hydration of acetylene, 714
—, —, oxidation of acetaldehyde, 885
—, —, — acetone, 432
Manganese acetylacetonate, catalyst, phenylcyclopentane, autoxidation, 907
Manganese alloys, catalyst, carbon from carbon monoxide, 229
Manganese borate, catalyst, pyrolysis of paraffins, 160
Manganese boro-phosphate, catalyst, hydration of butenes, 293, 294
—, —, — ethylene, 285, 286
—, —, — isobutene, 296
—, —, — propene, 292
Manganese, butyrate, catalyst, oxidation of acetaldehyde, 885
Manganese carbonate, catalyst, oxidation of methane, 881
Manganese chloride, catalyst, chlorination of ethylene, 495
—, —, — propene, 507
—, —, ether from ethyl alcohol, 331
—, effect on naphthenic acid salts, 1115
—, reaction with ethylene oxide, 560
—, — soaps, 1055
Manganese compounds, catalyst, nitration of toluene, 954
—, —, oxidation of *d*-α-pinene, 905
—, effect on color stability, 938
Manganese dioxide, absorption of hydrogen sulphide with, 1125
—, catalyst, oxidation of kerosene, 859, 860
—, —, — oils, 1047, 1054
—, —, — sodium sulphide, 465
—, —, pyrolysis of methane, 218, *227*
—, inhibitor, deterioration of ethylene oxide, 554

Manganese dioxide, promoter, in cracking, 112
—, —, pyrolysis of alcohol, 351
—, sweetening agent, 475
Manganese fluoride, catalyst, reaction of propene and hydrogen fluoride, 307
Manganese halides, catalyst, pyrolysis of paraffins, 158
—, —, reaction of dichloroethane and hydrogen fluoride, 747
—, —, — olefins and carbon monoxide, 625, 626
Manganese hydroxide, catalyst, reaction of sulphur and hydrocarbons, 467
—, for hydrogen sulphide removal, 458, 459
Manganese naphthenate, as antioxidant, 937
—, drying agent, 1115
—, promoter, oxidation of paraffin wax, 971
Manganese nitrate, catalyst, oxidation of acenaphthene, 955
Manganese oleate, catalyst, oxidation of paraffin wax, 971
—, —, — petroleum distillates, 962, 1059
—, —, — *d*-α-pinene, 905
Manganese oxide, catalyst, acetone from ethyl alcohol, 421, 423
—, —, chlorination of benzene, 781
—, —, hydration of acetylene, 714
—, —, in cracking, 137
—, —, ketones from ethyl acetate, 423
—, —, oxidation of aromatics, 942
—, —, — butyl alcohol, 880
—, —, — methane, 881
—, —, reaction of ethyl alcohol and steam, 422
—, —, — sulphur and hydrocarbons, 467
—, drying agent for isopropyl alcohol, 420
—, effect on ignition temperatures, 1000
—, in hydrogen sulphide removal, 458
Manganese phosphate, catalyst, hydration of ethylene, 284
—, —, — propene, 292
Manganese propionate, catalyst, oxidation of acetaldehyde, 885
Manganese salts, catalyst, acids from alcohols, 1051
Manganese soap, catalyst, oxidation of oils, 1044
—, —, — paraffin wax, 972
Manganese sulphate, promoter, hydration of ethylene, 283
Manganese vanadate, catalyst, oxidation of anthracene, 952
Mannitol, reaction with butylacetylene, 724
Marine plants, origin of petroleum, 21
Markownikov rule, 298
Mazout, cracking of, 103
—, definition of, 273
—, reaction with steam, 273
—, refining with charcoal, 1188
Medicinal compounds, preparation of, 690, 1080
Mellitic acid, preparation of, 822
Menthane, halogenation of, 776
Menthene, reaction with selenious acid, 446
—, — selenium dioxide, 895
Menthol, dehydrogenation of, 444
—, in motor fuels, 1035, 1039
Menthone, from menthol, 444
—, reaction with nitric acid, 850, 851
Mercaptans, acidity of, 469
—, alkylsulphonic acids from, 1066
—, as antioxidants, 486, 487, 937
—, as odorizing agents, 471

—, non-solvent in rubber cement, 374
—, reaction with acetone, 433
—, — amyl nitrite, 452
—, — phosphorus pentachloride, 452
—, solvent for ketene, 435
4-Methyl-3-ethyl-2-pentanone, preparation of, 445
4-Methyl-3-ethyl-3-penten-2-one, preparation of, 445
Methylethylpinacone, reaction with sulphuric acid, 678
Methyl formate, in reaction of acetone and amines, 428
—, preparation of, 1050
α-Methylglutaric acid, from methylcyclopentane, 876
β-Methyl glycerol, preparation of, 523
2-Methylheptane, from ethylene and isobutane, 601
—, from petroleum, 32
2-Methylhexane, from petroleum, 32
Methylhydrindene, pyrolysis of, 94
Methyl α-hydroxyisobutyrate, preparation of, 428
Methyl hypobromite, from methyl alcohol, 514, 531
—, reaction with aromatics, 531
—, — 1,3-cyclohexadiene, 531
Methyl hypochlorite, from methyl alcohol, 626
Methyl iodide, reaction with sodium acetylide, 722
Methyl isobutyl ketone, dewaxing agent, 433, 453
—, solvent for antioxidants, 919
Methylisopropenylacetone, preparation of, 444
Methylisopropylacetone, preparation of, 444
Methylisopropylbenzene, from sapropelite tar, 144
Methylisopropylbicyclononane, cracking of, 137
Methylisopropylethylene, polymerization of, 643, 645
unsym-Methylisopropylethylene, preparation of, 411, 645
Methylisopropylhexahydrofluorene, pyrolysis of, 94
Methyl isopropyl ketone, oxidation of, 450
Methyl mercaptan, preparation of, 526
—, reaction with ethylene chlorohydrin, 526
Methyl methacrylate, preparation of, 428
1-Methyl-3-methoxy-4-*ter*-butylbenzene, preparation of, 416
Methyl morpholine, utilization of, 585
Methylnaphthalene, from petroleum, 36, 40
—, from propane, 182
—, reaction with chlorinated Kogasin, 1253, 1254
Methyl naphthyl ketone, preparation of, 447, 448
Methyl nitrate, decomposition of, 1093
2-Methyl-2-nitropropane, preparation of, 1088
2-Methyl-1-nitro-1-propene, preparation of, 622
3-Methyloctane, from carbon monoxide and hydrogen, 1243
2-Methyl-1,3-octanediol, from 2-octene, 624
Methyl oleate, reaction with ozone, 902
Methylolurea, reaction with ethylene chlorohydrin, 525, 526
2-Methylpentane, from *n*-hexane, 198
—, from petroleum, 32
3-Methylpentane, detonation of, 1017
—, from *n*-hexane, 198
—, from petroleum, 32
2-Methyl-2-pentanol, from gasoline, 389
3-Methyl-2-pentanol, from 2-butene oxide, 588
4-Methyl-2-pentanol, from 4-methyl-2-pentene, 356
2-Methylpentene, from propyl alcohol, 173
2-Methyl-1-pentene, preparation of, 411
—, 2,2-dimethylbutanol from, 388
2-Methyl-2-pentene, oxidation of, 901
—, preparation of, 411
3-Methylpentene, reaction with phenols, 606
3-Methyl-2-pentene, oxidation of, 901
—, polymerization of, 643
—, reaction with aniline, 615
Methylphenol, reaction with propene, 605
Methylphenylacetylene, from benzylacetylene, 807
1-Methyl-3-phenylcyclopentane, from benzene, 207
Methyl phthalate, preparation of, 952
2-Methyl-2-propanol, *see* *ter*-Butyl alcohol
Methylpropene, *see* Isobutene
Methylpropylacetone, *see* 2-Acetylpentane
Methyl propyl ketone, from *sec*-pentanol, 443
—, from 2-pentene oxide, 589
2-Methylpyridine, reaction with aldehydes, 623
Methyl pyromucate, reaction with *ter*-amyl chloride, 818
Methylquinoline, from anthracene oil, 839
Methyl radical, formation of, 51, 52, 55, 79
—, reactions of, 50, 51
2-Methylsulphonyl-1-methylethane-1-sulphonic acid, salt, preparation of, 618
Methyltetrahydropicoline, reaction with formaldehyde, 623
p-Methyltolylbenzol, preparation of, 473
Methyl vinyl ketone, preparation of, 704, 705
Mineral oil, action of aluminum chloride on, 213, 216
—, carcinogenity of, 209
—, dewaxing of, 753
—, effect on ignition temperature, 998
—, ethylene glycol ethers in, 543
—, from petroleum, 28
—, in emulsifying agents, 1079
—, in foam-preventing agents, 1080

Phosphorus tribromide, reaction with cyclohexanol, 770
—, — cyclopentanol, 764
Phosphorus trichloride, catalyst, condensation of cyclohexane, 205, 1102
Phosphorus trisulphide, reaction with citric acid, 484
Photochemical decomposition, of hydrocarbons, 264-268
—, of ketones, 448-450
—, of organic lead compounds, 1022
Phthalic acid, from crude oil, 21
—, in demulsifying agents, 946, 947
—, reaction with glycols and alcohols, 542
—, solubility in polar compounds, 959
Phthalic anhydride, ammonium phthalate from, 958
—, benzaldehyde from, 950
—, benzoic acid from, 950-952
—, benzoyl chloride from, 952
—, decarboxylation of, 950-952
—, decolorization of, 958
—, drying agent for *ter*-butyl alcohol, 417
—, from fluorene, 954, 955
—, from kerosene, 966
Phthalic anhydride, from naphthalene, 861, 946, 950
—, in demulsifying agents, 946, 947
—, in dyes, 946
—, phthalyl chloride from, 731, 732
—, reaction with benzotrichloride, 794, 816
—, — butyl alcohol, 501
—, — carbon monoxide, 950
—, — carbon tetrachloride, 731, 732
—, — ethanolamine, 958
—, — ethylene glycol, 541
—, — methyl alcohol, 952
—, — paraffins, 1101
—, — steam, 952
—, — thionyl chloride, 945
—, resins from, 946
—, separation by polymerization, 960, 961
Phthalide, reaction with chlorobenzene, 789
Phthalimide, as antioxidant, 915
—, from ammonium phthalate, 958
Phthalones, from nitrogen bases, 834, 836
Phthalyl chloride, from phthalic anhydride, 731, 732, 794, 816
Picene, in petroleum coke, 145
Pickling inhibitors, aliphatic acids in, 1041
—, petroleum bases as, 841
Pickling solutions, aldehydes in, 890
—, hexamethylenetetramine in, 890
Picolines, as antioxidants, 917
α-Picolyalkine, *see* 2-(2′-Pyridyl) ethanol
Picric acid, catalyst, hydration of olefins, 297, 410
—, reaction with naphthalenes, 36
Pinacol, oxidation of, 536
Pinacolyl alcohol, dehydration of, 645
Pinene, as antiknock, 923, 1017
—, oxidation of, 855, 905
—, polymerization of, 645
—, pyrolysis of, 87, 88
—, reaction with formaldehyde, 624
—, — selenious acid, 446
—, stabilizing agent for methylene chloride, 728
Pinene hydrochloride, utilization of, 758
Pine oil, in lubricants, 1114
—, in motor fuel, 1035
Piperidine, extraction agent for asphalts, 1202
—, reaction with bromocyclohexane, 772, 773
—, — chlorocyclohexane, 768
—, — ethyl alcohol, 346
Piperonyl alcohol, preparation of, 958
Piperylene, from alcohols, 173
—, from kerosene, 144, 171
—, in gasoline, 144
Pitch, from petroleum, 7
—, removal with sulpho detergents, 1084
Pivalic acid, esterification of, 407
Plasticizing agents, alcohols as, 1112
—, ethylene glycol ethers in, 543, 544
—, from paraffin wax, 759, 1054
—, from polymer gasoline, 675
—, naphthenic esters as, 1112, 1120
Plastics, from ethylene dichloride and polysulphides, 499, 828
—, — and sodium thiosulphate, 829
—, from paraffin oil acids, 969
—, from sulphur chloride and olefins, 618, 619
—, wax acids in, 975
—, *see also* Resins
Platinum, catalyst, dehalogenation of haloalkyl ethers, 551
—, —, dehydrogenation of cyclohexane, 92, 179, 185
—, —, — hydrindenes, 95
—, —, — naphthenes, 31, 1150
—, —, ethers from acetals, 715
—, —, hydration of ethylene, 291
—, —, hydrogenation of carbon monoxide, 1049
—, —, — toluene, 347
—, —, — unsaturates, 1153, 1154
—, —, hydrolysis of chlorobenzene, 782
—, —, oxidation of aliphatics, 850, 851, 869, 1129
—, —, — aromatics, 942
—, —, — methane-ammonia mixture, 871
—, —, polmerization of olefins, 665
—, —, pyrolysis of 2-butene, 172
—, —, — ethylidene diesters, 718

Platinum, catalyst, pyrolysis of Kogasin, 155
—, —, — methane, 53
—, —, reaction of acetylene and amines, 719
—, —, — carbon and hydrogen, 1278
—, —, — methane and ammonia, 281
—, —, — nitric oxide and paraffins, 1091
—, —, sulphation of propene, 358
Platinum chloride, reaction with ethyl alcohol, 628
Platinum cyanide, catalyst, sulphation of isobutene, 391
Platinum halides, catalysts, hydrogen fluoride-dichloroethane reaction, 747
—, reaction with unsaturates, 628
Platinum-iridium alloy, catalyst, methane-nitric oxide reaction, 281
Platinum oxide, catalyst, hydrogenation of olefins, 899
—, —, oxidation of *d*-α-pinene, 905
Platinum-palladium, catalyst, oxidation of hydrocarbon gas, 851
Platinum-rhodium, catalyst, oxidation of hydrocarbon gas, 851
Platinum salts, catalysts, hydration of acetylene, 712
—, —, sulphation of isoolefins, 308
Polishing compositions, preparation of, 731, 1079
Polyalkene glycols, reaction with phthalic acid, 542
Polyamines, as antioxidants, 917
Polybasic acids, reaction with polyhydric alcohols, 541
Polybutyl amine, as antioxidant, 915
Polycarboxylic acids, as antioxidants, 941
—, from olefins, 629
—, plasticizing agents from, 542
Polychlorobenzene, chlorination of, 780, 781
—, from monochlorobenzene, 780, 781
—, in dyes, 782
Polychloroprene, chlorination of, 682
—, decomposition of, 682
—, properties of, 681
Polycyclic groups, effect on lubricating oil viscosity, 37
Polyethylene glycols, in cleaning agents, 545
—, esters and ethers in refrigerants, 545
—, solvent properties of, 545
Polyethylene oxides, structure of, 563
Polyethylene sulphone, properties of, 617
Polyglycerols, as lubricants, 545
Polyglycol arsenites, utilization, 545
Polyglycols, reactions of, 545
Polyhalogenated olefins, reaction with hypochlorous acid, 523
Polyhydric alcohols, from paraffin halides, 756
—, in emulsifying agents, 1074
—, oxidation of, 548
—, reaction with aldehydes, 544
—, — polybasic acids, 541, 542
Polyhydroxybenzenes, as antioxidants, 906, 918
—, effect on color stability, 926
Polymer gasoline, antiknock rating, 654
—, by catalytic processes, 662-666
—, by multi-stage process, 661, 662
—, by single-stage process, 656-658
—, by thermal process, 655
—, by two-stage process, 658-661
—, by Unitary process, 658, 659
—, from cracking gas, 97, 146
—, from Kogasin, 1255
Polymerization, during aquolization, 131
—, effect of catalysts, 633
—, in refining gasoline, 928, 929
—, of acetylene, 57, 89, 264-266, 680, 702, 703, 722
—, of aldehydes, 886, 889, 890
—, of alkyl halides, 811
—, of butadiene, 57, 387, 389, 650-652, 1116
—, of butenes, 81, 82, 386, 641-643, 895
—, of *ter*-butylethylene, 643, 645
—, of chloroprene, 681
—, of cyclohexene, 204, 645
—, of cyclopentadiene, 652, 654
—, of deuterioacetylene, 266, 725
—, of dichlorinated Kogasin, 814
—, of 1,2-dichlorobutadiene, 687
Polymerization, of dichlorobutene, 685
—, of *unsym*-dimethyl allene, 88, 650
—, of ethylene, 265, 283, 288, 290, 321, 646, 1041
—, of formaldehyde, 877, 887
—, of hexene, 643
—, —, free energy change, 1299, 1300
—, of isobutene, 296, 390, 633, 641-643
—, —, free energy change, 1300
—, of isopropylethylene, 387
—, of Kogasin, 1255
—, of methylallene, 649, 650
—, of methylisopropylethylene, 643, 645
—, of 3-methyl-2-pentene, 643
—, of olefins, 76, 107, 149, 160, 209, 395, 1041, 1252
—, of 2-pentene, 643
—, of 1-phenylbutadiene, 649
—, of pinene, 645
—, of propene, 288, 639-641
—, of propenylbenzene, 648, 649
—, of styrene, 647, 648, 805
—, of telluroformaldehyde, 51
—, of tetramethylethylene, 643, 645
—, of trimethylethylene, 203, 633
—, of unsaturates, 37
—, of vinylacetylene, 705
—, of vinylethinylcarbinol, 708
—, mechanism of, 631-633
Polymerized hydrocarbons, extraction from acid liquors, 397
Polymethylene alcohols, esterification of, 1118, 1119
Polynuclear hydrocarbons, in crude oil, 13
Polyolefin glycol ethers, solvents for nitrocellulose, 558
Polyoxymethylene, from formaldehyde, 877
Polyphenols, as antioxidants, 917
Polypropene sulphone, reactions of, 618
Polystyrene, depolymerization, 647
—, motor fuel from, 1040
—, preparation of, 647
Polysulphides, preparation of, 481, 482, 526
—, properties of, 482, 483
Polysulphones, preparation of, 618
Polythiophanes, preparation of, 484
Porcelain, catalyst, pyrolysis of ethyl alcohol, 155
—, —, — methane, 54, 180
—, —, reaction of propene oxide and ammonia, 587
Porphyrins, occurrence, 12, 20
Potassium, estimation in lubricants, 1164, 1165
Potassium acetate, catalyst, acetylation of cinnamaldehyde, 439
—, dehydration agent for ethyl alcohol, 329
—, from propene, 629
Potassium-alum, dehydration agent for *n*-propyl alcohol, 379
Potassium aluminate, catalyst, oxidation of toluene, 949
—, —, reaction of propene and metal hydroxides, 894, 895
Potassium amide, reaction with halobenzenes, 787, 810
—, — sulphur, 469
Potassium bisulphite, reaction with vinyl sulphone, 618
Potassium carbonate, catalyst, cracking, 112
—, —, ethyl acetate from ethyl alcohol, 340
—, —, oxidation of ethylene, 894
—, —, reduction of acetone, 432
—, —, — carbon dioxide, 1242
—, —, — carbon monoxide, 1223, 1228, 1231
—, in asphalt emulsions, 1216
—, reaction with ethylene dibromide, 532
Potassium chlorate, catalyst, hydroxylation of olefins, 532
—, —, reaction of chlorobenzene and ammonia, 787
Potassium chloride, catalyst, cracking, 112
—, —, oxidation of propane, 848, 873
—, —, reaction of benzene and dichloropentamethylenetetramine, 779
—, effect of ignition temperatures, 986, 987
—, in refining gasoline, 216
—, recovery from sylvanite solutions, 1063
—, solubility in isopropyl alcohol, 370

Potassium cresolate, reaction with chlorinated paraffins, 807
Potassium cyanide, reaction with potassium ethylene trichloroplatinate monohydrate, 628
Potassium dichromate, catalyst, oxidation of alcohols, 1057
—, —, — anthracene, 954
—, —, — glycols, 537, 546, 548
—, —, — methane, 870
Potassium ethylene trichloroplatinate monohydrate, reactivity of, 628
Potassium ferricyanide, for hydrogen sulphide removal, 1249
Potassium ferrocyanide, catalyst, chlorination of ethylene, 494
Potassium fluoride, fluorine from, 759
Potassium fluoride, reaction with formic acid, 887
Potassium hydrosulphide, catalyst, acetylene-hydrogen sulphide reaction, 721
Potassium hydroxide, antioxidant, 937
—, catalyst, condensation of acetone, 427
—, —, hydration of acetylene, 714
—, —, — ethylene, 291
—, —, hydrolysis of methyl chloride, 796
—, —, reaction of alcohols and ethylene oxide, 558
—, —, — and vinylacetylene, 706
—, dehydration agent for isopropyl alcohol, 364
—, desulphurizing agent, 434, 477
—, inhibitor, oxidation of ether, 335
—, reaction with alkyl halides, 804, 805
—, — butene chlorohydrin, 548
—, — *sec*-butyl alcohol, 407
—, — *ter*-butyl chloride, 412
—, — cyclohexadiene dibromide, 589
—, — 1,4-dichloro-2-butene, 685
—, — 3,4-dichloro-1-butene, 680, 681
—, — ethylene, 629
—, — ethylene dibromide, 504
—, — hexachlorobutane, 510
—, — hexene chlorohydrin, 589
—, — phenol and chlorobenzene, 788, 789
—, — tetrachlorobutane, 687
—, — tetrahydro-α-naphthol, 906
—, solubility in isopropyl alcohol, 375
Potassium iodide, reaction with butene dibromides, 1146, 1147
—, — tetralin peroxide, 906
—, — triethanolamine, 572
Potassium mercuric iodide, reaction with acetylene, 1123
—, — vinylacetylene, 708
Potassium methionate, preparation of, 820
Potassium nitrate, in heat-transfer media, 861, 862
—, promoter, hydration of isobutene, 294
Potassium oleate, in insecticides, 1059
Potassium permanganate, reaction with crudes, 21
—, — ethylene polymers, 203
—, — lead mercaptides, 475
—, — mercaptans, 1158
—, — olefins, 532
—, — paraffin wax, 974
—, — sulphur, 1161
—, — tetralin, 905
Potassium phenolate, reaction with ethylene dibromide, 505
—, — ethylene dichloride, 500
Potassium phosphate, removal of hydrogen sulphide by, 458
Potassium phthalimide, reaction with dibromocyclohexane, 772
Potassium silicate, promoter, in cracking, 112
Potassium sulphate, in cleaning agents, 1112
—, promoter, in cracking, 112
—, reaction with isopropyl ether, 381
Potassium sulphite, reaction with triiodomethane, 819
Potassium β-sulphoacrylate, preparation of, 820
Potassium thiocyanate, reaction with ethylene oxide, 564
Potassium vanadate, catalyst, oxidation of toluene, 949
Potassium vanadyl vanadate, catalyst, oxidation of toluene, 949
Pour point, definition of, 1176, 1177
Pour point depressor, from chlorinated wax, 758, 817
—, from paraffin wax, 215
Praesodymium oxide, catalyst, oxidation of aromatics, 942
Preservatives, *ter*-butyl phenols as, 818
—, copper naphthenates as, 1116
—, from chlorobenzenes, 782
Pressure, effect on cracking, 138, 139
—, — free energy change, 1296, 1298, 1299
—, — heat content, 1329
—, — ignition temperature, 992-996
—, — inflammability limits, 980
—, — polymerization of ethylene, 638, 639
—, — sulphation of ethylene, 299
—, effect on pyrolysis of aliphatics, 156, 188
—, — kerosene, 154
—, — olefins, 185
—, effect on reaction of propene and phosphoric acid, 358
—, increase on combustion, 1002-1005
—, reduced, definition of, 1319
—, relation to fugacity, 1322, 1323
Pressure-enthalpy-temperature relations, 1332, 1335
Pressure-volume product change, relation to heat content change, 1274
Pressure-volume-temperature relations, of hydrocarbons, 1320-1322
Printing ink, carbon black in, 250
—, naphthenates in, 1117
Progressive degradation method, for determination of naphthenic acids, 1104, 1111
Proofing agents, triethanolamine in, 577
Propadiene, *see* Allene
Propane, acetylene from, 61, 166, 168, 169, 187, 254
—, acids from, 858, 859, 862, 863
—, alcohols from, 858, 862, 863
—, aldehydes from, 858, 862, 863
—, aromatics from, 60, 61, 172, 181, 182
—, as motor fuel, 26, 1040
—, carbon black from, 219
—, chlorinated, utilization of, 751
—, combustion of, 241, 1003, 1004
—, commercial, specifications, 25
—, cracking of, 100, 101
—, cyclopentadiene from, 60, 182
—, energy of activation of, 58
—, entropy-temperature relations of, 1337-1340
—, estimation of, 1131, 1132
—, extraction agent, 31, 45, 262, 972, 1071, 1205
—, from *n*-butane, 201
—, from coke-oven gas, 165
—, from cyclopentane, 90
—, from gas oil, 140
—, from gasoline, 24
—, from hexadecane, 202
—, from hexane, 71, 257
—, from isobutene, 84
—, from isopentane, 69
—, from methane, 263
—, from methyl ethyl ketone, 449
—, from *n*-pentane, 68
—, from propylbenzene, 208
—, heat of combustion of, 15
—, hydrogen from, 60, 149, 275
—, ignition temperature of, 988, 989, 992, 993
—, inflammability limits of, 980, 984
—, inhibitor, decomposition of ethylene oxide, 554
—, in natural gases, 21, 22
—, ketones from, 858, 862
—, liquid hydrocarbons from, 160
—, methane from, 60, 151, 169
—, olefins from, 58-61, 149-153, 158, 160, 169, 873, 1284
—, oxidation of, 848, 850, 851, 858, 859, 862, 863, 869, 872-874
—, precipitant, 42, 45, 46, 1201
—, pyrolysis of, 57-61, 148-153, 158, 160, 166, 172, 181, 182, 555
—, reaction with chlorine, 749, 750
—, — ethylene, 601
—, — nitric acid, 1087
—, — steam, 275, 280

Propane, styrene from, 60, 182
—, utilization of, 25-27
1,2-Propanediol, oxidation of, 549
Propanol, *see* Propyl alcohol
Propanolamines, extraction agents for carbon dioxide, 587
—, — ethylene, 164
Propene, acetone from, 173, 292
—, acetylene from, 81, 187
—, allene from, 75
—, aromatics from, 639
—, as anesthetic, 1263
—, as motor fuel, 1040
—, butadiene from, 81
—, butene from, 641
—, chlorination of, 493
—, chlorohydrin from, 518
—, docedenes from, 639
—, effect on ethylene-sulphuric acid reaction, 324
—, — pulse rate, 1263
—, estimation in cracked gases, 1142
—, ethane from, 80
—, ethylene from, 80, 639
—, extraction of, 162, 163, 323, 324
—, from *n*-butane, 62-64
—, from carbon monoxide and hydrogen, 1241
—, from cyclohexane, 93
—, from cyclopentane, 90
—, from ethyl alcohol, 155
—, from ethylene, 636
—, from gas oil, 140
—, from gasoline, 136
—, from hexane, 257
—, from isobutane, 66
—, from isobutene, 85
—, from isopentane, 69
—, from isopropyl alcohol, 173, 365, 377
—, from isopropyl sulphate, 363
—, from ketones, 450
—, from methylcyclopentane, 90
—, from paraffin wax, 138
—, from *n*-pentane, 68
—, from 2-pentene, 87
—, from propane, 58-60, 149, 151, 153, 873
—, —, free energy change, 1284
—, from *n*-propyl alcohol, 173
—, hexenes from, 75, 79, 639, 641
—, hydration of, 288, 291-293
—, —, heat, 293
—, hydrogen from, 79, 81
—, ignition temperature of, 988
—, in commercial propane, 25
—, isobutyric acid from, 626
—, isopropyl alcohol from, 895
—, isopropyl mercaptan from, 462
—, methane from, 80
—, methyl radical from, 79
—, naphthenes from, 639
—, nonenes from, 639
—, oxidation of, 553, 629
—, paraffins from, 639
—, pentadecenes from, 639
—, pentenes from, 79, 641
—, polymerization of, 288, 639-641, 895
—, propene nitrosite from, 620
—, properties of, 15
—, *n*-propyl alcohol from, 292
—, *n*-propyl mercaptan from, 462
—, pyrolysis of, 75, 76, 79-81, 184, 187, 555
—, —, mechanism, 79
—, reaction with acetic acid, 307, 308, 359
—, — acetyl chloride, 612
—, — alkali hydroxides, 629, 894
—, — benzene, 591-593, 595-597
—, — benzoic acid, 308
—, — *ter*-butyl hypochlorite, 518
—, — carbon monoxide, 626
—, — chlorine and water, 516
—, — chloroacetic acid, 308
—, — α-chloromethyl ether, 613
—, — cresols, 605
—, — ethylene chlorohydrin, 529
—, — fluorene, 594
—, — hydrogen bromide, 307, 316
—, — hydrogen chloride, 306
Propene, reaction with hydrogen iodide, 316, 317
—, — hydrogen sulphide, 462
—, — hydroxy-benzoic acid, 609
—, — naphthalene, 593, 594, 596
—, — naphthalene sulphonic acid, 593
—, — nitrogen trioxide, 620
—, — phenol, 603, 604, 606
—, — phosphoric acid, 358
—, —, salicylic acid, 308, 607, 609
—, — stearic acid, 588
—, — sulphur dioxide, 617
—, — sulphuric acid, 161, 305, 306, 323, 356, 357, 359, 362, 363, 391, 1142
—, — sulphuric acid, mechanism, 357
—, — toluene, 594, 596
—, vinyl radical from, 75, 79
Propene chlorohydrin, from propene, 518
Propene dibromide, from propene, 508
Propene dichloride, azeotropic mixture with water, 507
—, 1-chloro-1-propene from, 508
—, dewaxing agent, 495, 507
—, drying agent for acids, 507
—, from propene, 506
—, in insecticides, 507
—, in lacquers, 751
—, paint remover, 507, 790
—, propene glycol from, 546
—, reaction with sodium cyanide, 507
—, solvent for cellulose acetate, 415
—, — cellulose acetopropionate, 507
—, — vinyl resin, 507
—, trichloropropane from, 508
—, *see also* 1,2-Dichloropropane
Propene dinitrate, preparation of, 587
Propene dinitrin, preparation of, 587
Propene glycol, dehydration agent, 538
—, estimation of, 537, 546
—, fatty acid esters, toxicity of, 549
—, from butyl lactate, 546
—, from glycerol, 547
—, from propene, 553
—, from propene dichloride, 546
—, hydroxy ketone from, 536
—, in brake fluid mixtures, 539
—, in cosmetics, 549
—, in heat transfer medium, 539
—, oxidation of, 536
—, properties of, 547
—, reaction with potassium dichromate, 537
Propene glycol carbonate, preparation of, 524, 525
Propene glycol formal, as solvent, 542, 543
Propene nitrosite, from propene, 620
Propene oxide, aldehydes from, 586
—, allyl alcohol from, 586
—, dimethyldioxane from, 579
—, from propene, 553, 586
—, hydrogenation of, 586
—, in adhesives, 586
—, polymerization of, 562
—, reaction with amines, 587
—, — ammonia, 585, 587
—, — cellulose phthalate, 588
—, — cetyl alcohol, 587
—, — diethyl magnesium, 586
—, — ethyl magnesium bromide, 586
—, — metal halides, 560
Propene sulphone, reaction with barium hydroxide, 617
Propenylbenzene, polymerization of, 648, 649
—, reaction with methyl hypobromite, 531
Propenylbenzoic acid, reaction with ozone, 902
p-Propenylmethoxybenzene, *see* Anethole
Propionaldehyde, decomposition of, 884
—, effect on ignition temperatures, 993
—, extraction agent, 44
—, from propene, 553
—, from propene oxide, 586
—, from *n*-propyl alcohol, 173
—, ozonization of, 887
Propionic acid, anhydration with propene chloride, 507
—, effect on sulphation of propene, 357
—, from *sec*-butyl alcohol, 407

Propionic acid, from carbon monoxide and hydrogen, 1244
—, from ethyl alcohol, 339
—, from ethylene, 446, 626
—, from methylethylacetylene, 904
—, from methyl ethyl ketone, 452
—, from paraffin wax, 971
—, from propene, 553
—, from sapropelite tar, 145
Propionitrile, extraction agent, 44
Propionyl chloride, reaction with *n*-propylbenzene, 447
Propyl acetate, extraction agent for polymerized hydrocarbons, 397
—, from propene, 308
Propyl alcohol, as antiknock, 1017
—, 1,3-dimethylbutadiene from, 173
—, esters from, 339
—, ethylene from, 173
—, extraction agent, 681, 1200
—, from pentane, 859, 864
—, from propene, 292
—, from propene oxide, 586
—, inflammability limits of, 980, 981
—, methyl-2-pentene from, 173
—, octane number of, 1028
—, propene from, 173
—, propionaldehyde from, 173
—, propyl ether from, 379
—, reaction with phenol, 384
—, stabilizing agent for tetrachloroethane, 743
Propylbenzene, from cyclohexanes, 94
—, from propenylbenzene polymer, 649
—, from sapropelite tar, 144
—, indene from, 156
—, reaction with propionyl chloride, 447
Propyl bromide, from propene, 307, 316
—, isomerization of, 316
Propyl chloride, dechlorination of, 805
—, from cracking gas, 302
Propylcyclohexane, from cyclohexanes, 93, 94
—, pyrolysis of, 91
Propylcyclopentyl carbinol, preparation, 765
Propyl disulphide, effect on color stability, 456, 924
Propyl ether, from propyl alcohol, 379
Propyl fluoride, from propene, 307
Propyl mercaptan, effect on color stability, 454
—, from propene, 462
—, reaction with cyclohexene oxide, 472
p-Propylpropiophenone, preparation of, 447
Propyl sulphide, preparation of, 479
Proteins, petroleum from, 19
—, precipitation with formaldehyde, 890, 891
Prussian-blue coloration, detection of alcohols by, 371
Pseudocritical points, definition of, 1318
—, determination of, 1318, 1319
Pseudocumene, from acetylene and benzene, 719
—, from kerosene, 36
—, from sapropelite tar, 144
—, from xylenes, 208
—, in crude oil, 35
Pseudonitroles, from nitroparaffins, 1093
—, reaction with aniline, 1094
Pseudonitrosite, from stilbene, 621
Pseudo-unimolecular reaction, definition of, 96
Pulse, effect of propene on, 1263
Pumice, catalyst, chlorination of methane, 726
—, —, decarboxylation of phthalic anhydride, 951
—, —, dechlorination of ethyl chloride, 805
—, —, esterification of ethyl alcohol, 304
—, —, in cracking, 144
—, —, pyrolysis of natural gas, 223
—, —, reduction of carbon monoxide, 1241
—, drying agent for *sec*-butyl alcohol, 400
Pyrazine, from cottonseed meal, 840
—, from ethanolamine, 568
Pyrene, action of aluminum chloride on, 215
—, chlorination of, 956
—, from natural gas, 220, 240
Pyrethrum, in insecticides, 1078
Pyridine, as antioxidant, 917
—, catalyst, hydration of olefins, 282
—, —, hydrolysis of vinyl acetate, 553
Pyridine, catalyst, oxidation of oils, 1044
—, —, reaction of ethylene dichloride and sodium acetate, 499
—, —, — mercaptans and ketones, 474
—, —, — vinylacetylene and hydrogen sulphide, 709
—, —, sulphation of alcohols, 1085
—, extraction agent, 977
—, for hydrogen sulphide removal, 458, 459
—, from cottonseed meal, 840
—, from petroleum, 833
—, peptizing agent for asphalts, 1196
—, reaction with monochlorocyclohexane, 768
—, — potassium ethylene trichloroplatinate monohydrate, 628
Pyridine bases, from acetylene, 719
—, from aldehydes, 885, 886
—, from pyroschists, 145
Pyridine homologues, from petroleum, 838
Pyridine oleate, in motor fuels, 1038
2-(2′-Pyridyl) ethanol, from 2-methylpyridine, 623
Pyrindane, isolation of, 841
Pyrocatechol, from *o*-dichlorobenzene, 785
—, reaction with methylene chloride, 828
Pyrocatechol ethers, preparation of, 825
Pyrocatechualdehyde, from heliotropin, 496
Pyrogallol, absorption of oxygen by, 1124
—, as antioxidant, 907, 913, 914, 916, 917
—, catalyst, hydrolysis of alkyl halides, 797, 801
—, decomposition of, 1124
—, effect on color stability, 926
—, inhibitor, polymerization of vinylacetylene, 705
Pyrogenesis, origin of petroleum, 17
Pyrolysis, effect of reaction chambers, 58, 63, 151-153, 159, 160, 188
—, free radicals from, 50-52
—, of acetals, 341
—, of acetylene, 88, 89
—, of allylcyclohexane, 93
—, of allylcyclohexene, 94
—, of allyltoluene, 96
—, of benzene, 95
—, of *n*-butane, 61-63, 150, 152
—, —, mechanism, 61, 62
—, of *n*-butenes, 81
—, of butylcyclopentanes, 91
—, of cracking gas, 136
—, of cyclohexane, 92, 93
—, of cyclohexylallene, 94
—, of cyclohexylallylene, 94
—, of cyclopentane, 90
—, of cylinder oil, 137
—, of diallyl, 88
—, of di-*ter*-butylethylene, 87
—, of dichlorobutanes, 678
—, of diisobutylene, 87
—, of 2,6-dimethylanthracene, 96
—, of dimethylcyclohexane, 93
—, of 2,5-dimethylhexane, 72
—, of esters, 340
—, of ethane, 55, 56, 150, 151, 158
—, of ethyl acetate, 341
—, of ethyl alcohol, 331, 347-353
—, of ethylbenzene, 95, 96
—, of ethylcyclohexane, 91
—, of ethylene, 56, 77
—, of ethylidene diacetate, 718
—, of gasoline, 154, 178, 179
—, of heptane, 71, 154
—, of *n*-hexane, 69-71, 154
—, of isoamylcyclopentane, 91
—, of isobutane, 65
—, of isobutene, 84, 85
—, of isopentane, 68, 69, 154
—, of kerosene, 137, 154, 155, 171
—, of Kogasin, 73, 155
—, of mercaptans, 479
—, of methane, 52, 53, 149, 158
—, of methylallene, 88
—, of methylcyclohexane, 91
—, of methylcyclopentane, 90, 91
—, of natural gas, 158-160
—, of nonane, 72
—, of octadecane, 73

Pyrolysis, of *n*-octane, 72
—, of *n*-pentane, 67, 149, 154
—, of pentenes, 85-87
—, of phenylcyclopentane, 91, 92
—, of pinene, 87
—, of propane, 57-59, 79, 150, 152, 153, 158, 160
—, of propylcyclohexane, 91
—, of spindle oil, 36, 37
—, of thiophene, 483
—, of 2,4,4, trimethyl-2-pentene, 87
—, of vinylcyclohexane, 93
—, of *p*-xylene, 96
—, stability of paraffins during, 49, 50
γ-Pyrone, from carbon monoxide and hydrogen, 1244
Pyrones, from wax acids, 979
Pyrophosphates, catalysts, reaction of ethylene glycol and aldehydes, 889, 890
Pyroschists, cracking of, 145
Pyrosulphates, catalysts, reaction of ethylene glycol and aldehydes, 889, 890
—, —, — glycols and ketones, 582
—, desulphurizing agents, 490, 929
Pyroxylin, solubility in ketones, 433
Pyrroles, extractants for asphalts, 1202
Pyruvic aldehyde, from acetone, 853

Q

Quartz, effect, ignition temperatures, 986
—, —, pyrolysis of methane, 53, 54
—, —, — propane, 58
—, in decarboxylation of zinc phthalate, 952
Quaternary ammonium compounds, from *ter*-alkylolamines, 572
Quinaldine, from acetylene and aniline, 719
—, from petroleum, 838
Quinhydrone, color stabilizer, 926
—, from hydroquinone, 382
Quinoline, catalyst, hydration of olefins, 282
—, for hydrogen sulphide removal, 458, 459
—, from anthracene oil, 839
—, from cottonseed meal, 840
—, from petroleum, 833, 838
—, in preparation of methacrylonitrile, 428
—, — olefins from alkylhalides, 804
—, reaction with dibromocyclohexane, 772
Quinolines, extractants, for asphalts, 1202
Quinone, as antiknock, 1018
—, from benzene, 942
—, from hydroquinone, 1277
Quinoneazine, condensation with cyclopentadiene, 693
Quinone compounds, inhibitors, polymerization of chloroprene, 681
Quinones, antioxidants for naphthenes, 937
—, from naphthalene, 953
—, reaction with diolefins, 175, 679, 688, 689, 699

R

β-Radiations, action on hydrocarbons, 267
Radon, action on cyclopentane, 267
—, — cyclopentene, 267
Raman spectra, determination of, 1181-1183
—, in petroleum analysis, 32
Rangoon paraffin wax, cracking of, 138
Rapeseed oil, cracking of, 136
Rapid-ignition point, definition of, 987
Rate of decomposition, in unimolecular reactions, 50
Rate of solution, of methane in oils, 9
Rayon, action of triethanolamine on, 578
—, viscose, sizing agent for, 587
—, —, softening agent for, 588
—, —, waterproofing of, 569
β-Rays, action on gaseous hydrocarbons, 268
—, — water gas, 268
Recycling, in cracking, 109
Red light, effect on iodine-ethylene reaction, 505
Red oil, as cleansing agent, 790
Reduced copper, removal of acetylene by, 171
Reduced equation of state, 1319
Reduced pressure, definition of, 1319
Reduced temperature, definition of, 1319
Reduced volume, definition of, 1319
Reduction, acetaldol to 1,3-butene glycol, 547
—, of aldehydes, 885, 889
—, of benzoquinone, 953
—, of carbon dioxide, 1247
—, of carbon monoxide, free energy change, 1303-1305
—, of diolefins to monolefins, 698
—, of maleic acid, 945
—, of naphthenic acids, 1118
—, of nitroparaffins, 1094, 1095
Reference standards, in knock rating, 1024-1027
Refining, effect on stability of oils, 940
—, of paraffin wax, 39
—, of petroleum, 31
—, of sulphonates, 1072, 1073
—, use of acetic acid, 625
—, — aldehydes, 625
—, — carbon tetrachloride, 731
—, — clay adsorbents, 135
Refining agent, sulphuric acid as, 1069, 1070
—, for gasoline, 927-930
Refining methods, effect on color stability, 927
Reforming, of naphtha, 105
Refractive index, in analysis of gasoline, 144
Refractivity index, 1178
Refractivity intercept, 1178
Refrigerants, chloroethanes in, 745
—, chlorofluoromethanes, 737
—, chloromethanes in, 727
—, dichlorobenzene in, 790
—, polyethylene glycol derivatives in, 545
Repressuring, with natural gas, 9
Residual oils, oxidized to alcohols, 1050
—, — asphalts, 1043
Residuum tar, motor fuels from, 136
Residuums, characterization factor of, 1308
Resinic acid, glycol ethers from, 543
Resins, adsorption agents for, 1188
—, antioxidants for naphthenes, 937
—, as sizing agents, 1189
—, by chlorination of tar, 756
—, by co-polymerization of olefins and diolefins, 216
—, by oxidation of petroleum, 1057, 1058
—, decolorization of, 216
—, extraction from oils, 1188, 1189
—, from acetylene, 701
—, from aldehydes, 886, 890, 1081
—, from aluminum chloride sludge, 217
—, from chlorinated hydrocarbons, 814, 815
—, from 1-chlorobutadiene, 685
—, from coniferous wood, 46
—, from cracked gasoline, 216, 625
—, from cracking tars, 147
—, from dichlorobutenes, 685
—, from esters of polyhydric alcohols, 541
—, from ethane, 257
—, from ethylene and sulphur chloride, 618, 619
—, from ethylene chlorohydrin, 525, 526
—, from indene, 155
—, from ketones, 453
—, from monovinylacetylene, 685
—, from olefins and aldehydes, 625
—, from olefins and sulphur dioxide, 618
—, from petrolatum and carbon tetrachloride, 732
—, from petrolenes, 1202
—, from phthalic anhydride, 946
—, from polypropene sulphone, 618
—, from primary tars, 729
—, from residual hydrocarbons, 1189
—, from styrene, 155
—, from sulphonic acids, 1081
—, glycol ethers from, 543
—, in alkali sludge, 1105
—, in chewing gum bases, 1189
—, iodine numbers of, 216, 217
—, oil-soluble, preparation of, 818
—, oxidized to asphaltenes, 1189
—, petroleum, uses of, 147
—, reaction with castor oil, 217
—, — glycerol, 217
—, solvents for, 453, 1188
—, substitutes for shellac, 625
Resolution, of azeotropic mixture, 30

Resonance isomerization, definition of, 442
Resorcinol, color stabilizer, 926
—, reaction with ethylene chlorohydrin, 525
—, — acetylene, 715
—, — secondary alcohols, 403, 409
—, stabilizer for methyl chloride, 727
Rhenium, catalyst, dehydrogenation of alcohols, 420
—, inhibitor, decomposition of ketones, 420
Rhenium halides, catalyst, dehydrogenation of hydrocarbons, 158
Rhodanates, as insecticides, 1059
—, preparation of, 1059
Rice mechanism, pyrolysis of neopentane, 69
—, — *n*-pentane, 68
Ricinoleic acid, detergent properties of soaps from, 1113
—, reaction with isobutyl alcohol, 1086
Ring formation, inhibitors of, 138
Roofing compositions, asphalts in, 1213
Rosin, for stabilizing carbon tetrachloride, 730
—, in emulsifying agents, 1114
—, in insecticides, 790
—, purification of, 46
—, reaction with hydrogen sulphide, 466
—, soluble oil from, 538
Rosin soap, in vulcanization of rubber, 1078
Rosin soaps, detergent properties of, 1113
—, in asphalt emulsions, 1218
—, in emulsifying agents, 1079
Rubber, autoxidation of, 905
—, carbon black in, 246, 249
—, channel black in, 250
—, chlorinated, in coating composition, 543
—, di-*n*-propyl ketone, solvent for, 443
—, mastication of, 1078
—, motor fuel from, 136
—, synthetic, from acetylene, 701
—, —, from butadiene, 173, 672, 673, 674
—, —, uses of, 674
—, —, vulcanization of, 674
Rubber, vulcanization of, 468, 1078
Rubber cement, improving film-breaking tendency of, 374
—, reducing viscosity of, 374
Rubber latex, use in asphalt emulsions, 1218
Rubber-like material, from 1,2-dichlorobutadiene, 687
—, from polyprene, 682
Rubber sponge, triethanolamine in manufacture of, 577
Rubidium carbonate, promoter, reduction of carbon monoxide, 1228
Rubrene, oxidation of, 848, 849
Ruthenium, catalyst, reduction of carbon dioxide, 1242

S

Salicylaldehyde, in determination of acetone, 424
Salicylic acid, color stabilizer for gasoline, 926
—, in asphalt emulsions, 1219
—, reaction with ketene, 438
—, reaction with propene, 308, 607, 609
—, solubility of, 959
Samarium oxide, catalyst, oxidation of aromatics, 942
Sand molds, preparation of, 731
Saponifiable substances, adsorption of, 732
Saponification number, determination of, 1166, 1167, 1195
Saponin, use, in cleaning agents, 543
Sapropelite tar, cracking of, 135, 143-145
—, polymerization of olefins from, 211
Sapropels, definition of, 975
—, oxidation of, 975
Saturates, as antiknocks, 1016
Sawdust, use in cracking, 111
Scouring agents, dichloroethane in, 745
—, triethanolamine in, 577
Sea water, bromine from, 504
Sebacic acid, alkoxyalkyl ester, use as plasticizer, 544
Second order reaction, definition of, 501
Selenious acid, use in preparation of unsaturated ketones, 446
Selenious oxide, in oxidation of acetone, 432
Selenium, catalyst, bromination of benzene, 790, 791
—, —, cracking, 113
—, —, pyrolysis of hydrocarbons, 94, 158, 189, 191
—, reaction with acetylene, 720
—, use in lubricants, 469
—, use in refining gasoline, 669
Selenium charcoal, dehydrogenation catalyst, 94
Selenium dioxide, as oxidizing agent, 852, 853, 895, 900, 957
—, reaction with ketones, 853
—, — aromatics, 957
—, — olefins, 895, 900
Selenium oxide, catalyst, oxidation of olefins, 553
Selenium oxychloride, catalyst, oxidation of benzaldehyde, 957
Selenophene, preparation, 720
Semenov's law, 997, 998
Semicarbazides, as antioxidants, 915
Sesquiterpenes, preparation of, 688
Shale oil, aquolysis of, 132
—, green oil from, 242
—, hydrocarbons in, 32, 33, 35
—, medicinal products from, 1080
—, substitute for petroleum, 9
Shale-oil gasoline, *n*-heptane from, 32
Shale-oil tar, carboids from, 1194
—, reaction with sulphuric acid, 1069
Shaving preparations, 540, 1081
Shukhov-Kapelyushnikov cracking process, 123
Silent discharge, action on acetylene, 258
—, — aromatics, 259, 260
—, — olefins, 258, 259
—, — paraffins, 257, 258, 263
—, dehydrogenation by, 256
—, in dewaxing, 263, 264
—, in methane oxidation, 264
—, in vapor-phase cracking, 263
—, polymerization with, 210, 256, 263
—, reduction with, 264
Silica, catalyst, chlorination of toluene, 793
—, —, cracking, 128
—, —, hydrolysis of chlorobenzene, 782, 783
—, —, oxidation of aromatics, 942
—, —, ozonization of gasoline, 1045
—, —, polymerization of olefins, 1042
—, —, pyrolysis of hydrocarbons, 71, 180, 227
—, —, reaction of methane and carbon monoxide, 1050
—, —, — olefins and sulphuric acid, 323
—, —, reduction of carbon monoxide, 1228, 1239, 1240, 1241, 1249
—, impurity in acetylene black, 244
Silica dust, effect, on inflammability limits, 985
Silica gel, catalyst, cracking, 112
—, —, hydrolysis of mesityl oxide, 423
—, —, isomerization of propene oxide, 586
—, —, nitration of benzene, 1092
—, —, oxidation of hydrocarbons, 444, 882, 949
—, —, polymerization of diolefins, 171, 667
—, —, — olefins, 642, 666
—, —, pyrolysis of aliphatics, 189
—, —, — 2-butene, 172
—, —, reaction of acetylene and acetic acid, 717
—, —, — ethyl chloride and carbon monoxide, 830
—, —, — ketene and hydrogen chloride, 439
—, —, — phenol and lead tetraethyl, 823
—, —, — propene and hydrogen halides, 306, 307, 316
—, desulphurizing agent, 398, 489
—, selective adsorbent, 31, 165, 732, 1046, 1155, 1188
Silicates, catalyst, ozonization of gasoline, 1045
—, —, reaction of amines and alcohol, 614
Silicic-acetic anhydride, reaction with acids, 1116
Silicic acid, use in refining gasoline, 669
Silicon, acid salts as catalysts, reaction of olefins and carbon monoxide, 626
—, catalyst, chlorination of benzene, 778
—, —, cracking, 115
—, —, dehydrogenation of acenaphthene, 955

Silicon, catalyst, polymerization of acetylene, 89
—, —, pyrolysis of aliphatics, 189
—, —, — benzene, 191
—, —, — saturated hydrocarbons, 159
—, —, reaction of carbon disulphide and chlorine, 730
—, —, reduction of carbon monoxide, 1228
—, in alloys, to reduce corrosion, 134
Silicon carbide, catalyst, oxidation of naphthalene, 946
—, in pyrolysis reactions, 167, 168, 189, 192
Silicon carboxylates, catalysts, hydrogenation, 1116
Silicon halides, catalyst, dehydrogenation of hydrocarbons, 158
Silicon tetrachloride, in refrigerants, 738
—, reaction with cyclohexane, 1102
Silicon tetrafluoride, fluorinating agent, 736
Silicotungstic acid, catalyst, ethylene oxidation, 894
—, test for nitrogenous substances, 925
Sillimanite, use in dehydrogenation of alcohol, 1051, 1052
Silver, catalyst, combustion of carbon monoxide, 1000
—, —, cracking, 112
—, —, dimerization of acetylene, 705
—, —, ethers from acetals, 715
—, —, ethyl alcohol from ether, 333
—, —, fluorination of benzene, 791
—, —, higher alcohols from ethanol, 340
—, —, hydrolysis of chlorobenzene, 782
—, —, hydrolysis of *o*-dichlorobenzene, 785
—, —, oxidation of alcohols, 420, 421, 844, 878-880, 1051
—, —, — ethylene, 552, 553, 893
—, —, — methane, 869
—, —, — olefins, 552, 553, 586, 893
—, —, — paraffins, 874
—, —, — propene, 586
—, —, sulphation of ethylene, 323
—, —, — propene, 358, 360
—, —, reaction of ketones and alcohols, 443
—, —, reduction of carbon monoxide, 1229, 1241
—, effect, on ignition temperature, 986
—, in estimation of sulphur, 1162, 1163
—, in test for aldehydes, 885
Silver acetate, in preparation of cycloolefin oxides, 589
Silver bromate, solubility in isopropyl alcohol, 370
Silver cyanide, catalyst, preparation of *ter*-butyl alcohol, 391
—, for hydrogen sulphide detection, 466
Silver fluoride, reaction with choloroform and calcium fluoride, 737
Silver halide, catalyst, dehydrogenation of hydrocarbons, 158
—, —, dichloroethane-hydrogen fluoride reaction, 747
Silver hydroxide, reaction with *ter*-bromides, 413
—, stabilizer, for ether, 336
Silver nitrate, extraction agent for butadiene, 174
—, in estimation of acetylene, 1144, 1145
—, — mercaptans, 1158, 1159
—, — sulphur, 1157
—, promoter, hydration of isobutene, 296
—, reaction with asphaltogenic acids, 1195
Silver oxalate, oxidation catalyst from, 553
Silver oxide, carbon monoxide estimation with, 1125
—, catalyst, ketone-alcohol reaction, 443
—, —, oxidation of alcohols, 844
—, —, — methane, 869
—, —, — olefins, 553
—, —, — *d*-α-pinene, 905
—, —, — toluene, 950
—, stabilizer, for ether, 336, 381
Silver perchlorate, catalyst, iodination of cyclohexene, 774
Silver salts, catalysts, hydration of vinylacetylene, 705
—, —, oxidation of toluene, 950
—, —, polymerization of olefins, 634
—, —, sulphation of isoolefins, 308
—, —, — propene, 357, 358
—, effect on stability of lubricants, 938
Silver sulphate, catalyst, hydration of ethylene, 283, 286
—, —, hydration of propene, 291, 292
—, —, reaction of propene and phosphoric acid, 358
—, —, sulphation of butene, 387
—, —, — ethylene, 322, 323
—, —, — propene, 358
—, in estimation of olefins, 1124, 1135
Silver vanadate, catalyst, oxidation of anthracene, 952
Sizing agents, from propene oxide, 587
—, from triethanolamine, 577
—, petroleum resins in, 1189
—, sulphonaphthenic acid salts as, 1118
—, urethans as, 569
Slack wax, polymerization of, 212
Slop wax, extraction of, 972
—, oxidation of, 972
Sludge formation, in oils, 937, 939, 940
Sludge value, of lubricants, determination of, 934
Soap powders, wax acids in, 978
Soaps, from wax acids, 970
—, in asphalt emulsions, 1219
—, in fungicides, 969
—, in insecticides, 969, 1077
—, in lubricants, 968
—, water-insoluble, preparation of, 1055
Soda-lime, as extraction agent, 1106, 1107
—, catalyst, depolymerization, 1040
—, —, polymerization of dichlorobutenes, 685
Sodamide, desulphurizing agent, 489
—, in preparation of ethyl propiolic acid, 511
—, reaction with 1,2-dibromobutane, 829
Sodium, catalyst, alkyl halides-aromatics reaction, 827
—, —, cracking, 113
—, —, ethylene oxide from chlorodimethyl ether, 551
—, —, polymerization of butadiene, 651, 673
—, —, pyrolysis of olefins, 76
—, desulphurizing agent, 489
—, in estimation of lubricating greases, 1164, 1165
—, — sulphur, 1162
—, — water in gasoline, 1168
—, in refining gasoline, 669
—, reaction with alkyl bromides, 826
—, — aryl bromides, 827
—, — *ter*-butyl alcohol, 418
—, — halogenated hydrocarbons, 722
—, — methylacetylene, 722
—, — naphthalene, 957, 958
Sodium acetate, dehydrating agent, 329
—, from ethyl alcohol, 342
—, in estimation of mercaptans, 1159
—, reaction with benzyl chloride and acetic acid, 794
—, — ethylene dichloride, 499
—, to stabilize acetaldehyde, 713
Sodium acetylide, reaction with iodine, 711
—, — methyl iodide, 722
Sodium acid sulphate, catalyst, ethers from *ter*-alcohols, 413, 414
—, —, reaction of ethylene glycol and paraformaldehyde, 582
—, —, — propene and acetic acid, 308
Sodium alcoholates, catalysts, alcohol-vinylacetylene reaction, 705
—, reaction with alkyl halides, 826
Sodium-aluminum-borotitanate, catalyst, decomposition of ether, 335
Sodium amalgam, in reduction of nitrolic acids, 1094
Sodium arsenate, absorption of chlorine by, 744
—, inhibitor, corrosion of iron, 574
Sodium bicarbonate, reaction with ethylene dichloride, 532
—, — propene dichloride, 546
Sodium bisulphite, autoxidation of, 905
—, catalyst, 1,5-dihydroxynaphthalene-ethanolamine reaction, 569
—, —, oxidation of petroleum, 966
—, reaction with ethylene oxide, 565
—, — ketones, 448

Sodium bisulphite, reaction with tetralin peroxide, 906
—, — vinyl sulphones, 618
Sodium borate, effect on asphalt emulsions, 1216
Sodium *ter*-butylate, formation of, 418
Sodium carbonate, catalyst, cracking, 112
—, —, oxidation of paraffin wax, 971
—, — reduction of carbon monoxide, 1229
—, effect on asphalt emulsions, 1216
—, — naphthenic acid soaps, 1113
—, extraction agent, naphthenic acids, 1105, 1107
—, inhibitor, dehydration of alcohols, 420
—, reaction with ethylene chlorohydrin, 533, 534
—, — ethylene dichloride, 532, 533
—, — propene dichloride, 546
—, sulphur estimation by, 1127
Sodium chloride, as demulsifying agent, 1108, 1111, 1112
—, catalyst, cracking, 112
—, —, decarboxylation of phthalic anhydride, 950
—, effect on asphalt emulsions, 1215, 1216, 1218
—, — methane pyrolysis, 54
—, in estimation of olefins, 1143
—, in refining of gasoline, 216
—, in refining of isopropyl alcohol, 365
—, solubility in isopropyl alcohol, 370
Sodium copper silicate, catalysts, hydrolysis of chlorobenzene, 783
Sodium cyanide, reaction with amyl chloride, 822
—, — olefins, 305
—, — propene dichloride, 507
Sodium deutroxide, reaction with chloral deuterate, 729
Sodium diphenylmethyl, catalyst, polymerization of butadiene, 651
Sodium ethoxide, catalyst, reaction of mercaptans and ketones, 474
Sodium ethyl sulphonate, preparation of, 819
Sodium formate, in hydrolysis of *o*-dichlorobenzene, 785
Sodium hydride, catalyst, cracking, 115
Sodium hydrosulphide, oxidation of, 465
—, reaction with mercaptans, 480
Sodium hydroxide, bromine absorption by, 1143
—, catalyst, condensation of acetone, 427
—, —, — dichlorobutenes, 685
—, —, cracking, 136
—, —, hydration of ethylene, 291
—, —, oxidation of paraffin wax, 971
—, —, reaction of ethylene oxide and alcohols, 558
—, —, — oxidized paraffin and pentaerythritol, 1055
—, demulsifying agent, 1111, 1112
—, desulphurizing agent, 489
—, effect on naphthenic acid soaps, 1114
—, extraction agent, naphthenic acids, 1105-1107
—, in dechlorination of 1,2,3,4-tetrachlorobutane, 687
—, in determination of naphthenic acids, 1104
—, in drying of isopropyl alcohol, 364
—, in estimation, of sulphur, 1162
—, in formation of keto-alcohols, 433
—, in preparation of asphalt emulsifiers, 1217
—, in preparation of ethylenediamine, 497
—, in refining gasoline, 669, 670
—, in separation of wax acids, 976
—, reaction with benzyl chloride and ethylene glycol, 543
—, — *sec*-butyl alcohol, 407
—, — cyclohexene peroxide, 898
—, — ethyl alcohol, 342
—, — ethylene dibromide, 533
—, — ethylene dihalides and carbon dioxide, 532
—, — ethylene halohydrins and carbon dioxide, 532
—, — ethyl hypochlorite, 551
—, — olefin halohydrins, 588
—, — polypropene sulphone, 618
—, — sulphur, 828
—, sweetening agent, 475, 477
Sodium hypochlorite, in diisobutylene oxidation, 895
—, reaction with mercaptans, 470
—, — monovinylacetylene, 687
Sodium hypoiodide, reaction with acetylene, 711
Sodium iodide, reaction with triethanolamine, 572
Sodium isopropylxanthate, utilization of, 378
Sodium lauryl sulphate, as detergent, 1084
—, in fireproofing, 1086
—, in de-inking agents, 1086
Sodium mahogany sulphonate, use in grease, 1079
Sodium metaphosphate, catalyst, hydration of ethylene, 287
Sodium metasilicate, emulsifying agent for asphalts, 1217
Sodium methoxide, catalyst, reaction of mercaptans and olefin oxides, 472
—, reaction with difuroyl peroxide, 1152
—, — chlorocyclohexane, 768
Sodium naphthenate, catalyst, oxidation of petroleum, 964
—, uses of, 1113, 1114
Sodium naphtholate, reaction with ethylene dichloride, 500
—, — glycols, 543
Sodium nitrate, in heat-transfer, 861, 862
Sodium nitrite, reaction with acetic acid and β-phellandrene, 620
Sodium nitroprusside, for hydrogen sulphide detection, 466
—, in estimation, of alkyl sulphides, 1159
—, — thiophenol, 1159, 1160
—, reaction with asphaltogenic acids, 1195
Sodium oleate, catalyst, hydrolysis of amyl chloride, 801
—, detergent properties of, 1084
—, in hydrolysis of chlorobenzene, 783
—, surface tension of, 1065, 1066
Sodium oleyl sulphate, as detergent, 1084
Sodium oxide, extraction agent, naphthenic acids, 1105
Sodium palmitate, catalyst, oxidation of petroleum, 964
Sodium peroxide, in estimation of sulphur, 1161, 1162
—, oxidizing agent, for cracked hydrocarbons, 490
—, sweetening agent, 476, 478
Sodium persulphate, oxidizing agent for cracked hydrocarbons, 490
Sodium phenolate, reaction with carbon monoxide and alcohols, 957
—, — chlorobenzene and phenol, 784, 785
—, — ethylene dichloride, 825
—, — naphthenic esters and acids, 1120
Sodium phenyl, reaction with ethylene oxide, 563
Sodium phosphate, effect on asphalt emulsions, 1216
Sodium plumbite, in ozonization of gasoline, 1045
—, in purification of isopropyl alcohol, 365
—, reaction with ethyl iodide, 829
—, — mercaptans, 397, 408, 474, 475
—, sweetening agent, 457, 475, 476, 926
Sodium polysulphide, reaction with ethylene and sulphur chloride, 618, 619
—, — ethylene dichloride, 499, 828
—, sodium thiosulphate from, 465
—, sweetening agent, 477
Sodium pyrosulphate, catalyst, hydration of ethylene, 288
Sodium silicate, catalyst, hydration of acetylene, 714
—, in asphalt emulsions, 1216, 1220
—, inhibitor, dehydration of alcohols, 420
Sodium stannate, in fireproofing agents, 1086
Sodium stearate, detergent properties of, 1084
—, in hydrolysis of chlorobenzene, 783
—, in lubricating oils, 1114
—, reaction with ethylene dichloride, 499
Sodium sulphate, confining agent in gas analysis, 1124
—, effect on naphthenic acid soaps, 1114
—, in cleaning agents, 1112
Sodium sulphide, catalyst, ripening of alkali cellulose, 464
—, in insecticides, 1060
—, reaction with chlorobenzene, 785
—, — ethylene dichloride, 499
—, — ethyl iodide, 819
—, sodium thiosulphate from, 464-466
Sodium sulphite, reaction with benzal chloride, 794
—, sodium thiosulphate from, 465

Sodium sulphonates, in demulsifying agents, 1075
—, in detergents, 1069, 1073
—, in dust fixatives, 1079
—, in oxidation of aromatics, 953
—, surface tension of, 1065-1067
Sodium thiocyanate, reaction with dodecyl chloride, 822
Sodium thiosulphate, from sodium sulphides, 464-466
—, from spent doctor solution, 476
—, in estimation of acetone, 424
—, — gum, 912
—, — sulphur, 1162
—, reaction with ethylene chloride, 829
Sodium triphenylmethyl, catalyst, polymerization of butadiene, 651
Sodium vanadate, inhibitor, corrosion of steel, 574
Sodium zincate, in ozonization of gasoline, 1045
Softening agents, ethylene glycol ethers in, 558
—, from paraffin wax, 1054
—, naphthenic acids in, 1112
—, sulphuric acid esters in, 1112
—, urethans in, 569
—, wax acids in, 975
Softening point, of asphalts, determination of, 1206
Softening point-penetration index, of asphalts, 1208, 1209
Solar oil, oxidation of, 940, 964, 965
Soligen driers, definition of, 1115
Sols, metallic oxides, preparation of, 560
Sorbitol, reaction with ethyl chloride, 826
Soybean oil, cracking of, 136
Soy beans, lecithin from, 728
Sovprene, definition of, 681
Specific dispersion, definition of, 1177
Specific gravity, characterization factor from, 1307, 1309, 1310
—, critical temperature from, 1311, 1312, 1313
—, heat content from, 1327
—, in analysis of gasoline, 144
—, molecular weight from, 1311
—, specific heat from, 1323, 1325
Specific heat, definition of, 1306
—, determination of, 1323, 1325
—, entropy change from, 1277
Specific refraction, determination of, 1177, 1178
Specific parachor, effect on octane number, 1030, 1031
Spectroscope, in estimation of lead tetraethyl in gasoline, 1165
Spindle oil, in detergents, 1073
—, sulphonic acids from, 1074
Spirillum aestuari, decomposition of sulphur compounds by, 490
Spreading coefficient, of asphalts, 1213
Stability number, of lubricants, 933
Standard reference state, definition of, 1278
Squalene, from naphthenic residues, 21
Stannic chloride, catalyst, polymerization of isobutene, 642
—, —, polymerization of styrene, 647
—, —, reaction of acetylene and hydrogen chloride, 716
—, —, — alkylacetylenes and acetyl chloride, 724
—, —, — olefins and acid chlorides, 613
—, reaction with cyclohexane, 1102
—, to determine instability of motor fuel, 911
Stannic oxide, catalyst, methane oxidation, 871
—, —, preparation of cuprene, 704
Stannous chloride, catalyst, chlorination of dioxane, 581
—, nitromethane reduced by, 1094
Stannous phosphate, catalyst, hydrolysis of methyl chloride, 796
Starch, in asphalt emulsions, 1219
—, in gum estimation, 912
—, promoter, reduction of carbon monoxide, 1229, 1230
Stationary flame, theory of, 1006, 1007
Steam, diluent, conversion of propene oxide to allyl alcohol, 586
—, —, oxidation of ethylene, 552, 553, 893
—, —, — kerosene, 860
—, —, — petroleum oils, 1054
Steam, diluent, pyrolysis of hydrocarbons, 93, 156, 178, 190, 192
—, effect on cracking, 127, 128, 131-133
—, — electrical decomposition of methane, 255
—, in activation of carbon, 165, 232
—, in dehydrogenation of menthol, 444
—, in desorption of olefins from charcoal, 164
—, in refining asphaltic residues, 1199
—, pressure-volume-temperature relations of, 1321, 1322
—, reaction with aromatics, 273
—, — butane, 275, 280
—, — carbon monoxide, 871
—, — coke, 1247
—, — coke-oven gas, 1247, 1248
—, — ethyl alcohol, 421
—, — ethyl ether, 421
—, — hydrocarbons, 273, 277, 278, 280
—, — mesityl oxide, 423
—, — methane, 220, 270-273, 276-279, 870, 1246, 1247
—, — natural gas, 276
—, — olefins, 270, 271, 273
—, — olefins and carbon monoxide, 446
—, — petroleum oils, 272, 273
—, — propane, 275, 280
Stearates, catalysts, oxidation of paraffin wax, 971
Stearic acid, bacterial action on, 19
—, catalyst, preparation of ethyl acetate, 304
—, foam-preventing agents from, 1080
—, in candle wax, 543
—, in shaving preparations, 1081
—, reaction with olefins, 588
—, voltolization of, 261
Stearine pitch, in asphalt emulsion preparation, 1216
Steel, catalyst, polymerization of ketene, 441
—, —, pyrolysis of hydrocarbons, 149, 159, 181
Steric hindrance, effect in polymerization, 632
Stilbene, bromination of, 514
—, formation in selenium-acetylene reaction, 720
—, hydrogenation of, 207
—, oxidation of, 895
—, reaction with nitrogen oxides, 621
—, — ozone, 902
Strecker reaction, 819, 820
Strontium boro-phosphate, catalyst, hydration of ethylene, 285
—, —, — propene, 292
Strontium carbonate, catalyst, ketones from ethyl acetate, 423
—, —, polymerization of ethylene oxide, 562
Strontium naphthenates, in inks, 1117
Strontium nitrate, solubility in isopropyl alcohol, 370
Strontium oxide, catalyst, polymerization of ethylene oxide, 562
—, —, reduction of carbon monoxide, 1240
Strontium phosphate, catalyst, hydration of ethylene, 287
—, —, — propene, 292
Structure, effect on entropy change, 1286, 1288-1293
—, — free energy of formation, 1281, 1284, 1286, 1288
—, — stability of aromatics, 1285
Styrene, effect of lead tetraethyl on, 1022
—, ethylcyclohexane from, 1154
—, from acetylene, 718
—, from α-chloroethylbenzene, 805
—, from cracking gases, 645, 646
—, from ethylbenzene, 96, 156, 159
—, from ethylene and benzene, 645
—, from natural gas, 155, 183
—, from propane, 60, 182
—, from vinylacetylene, 705, 706
—, hydrogenation of, 1154
—, mechanism of formation, 156
—, 2 phenyl-1,3-propanediol from, 625
—, polymerization of, 647, 648, 805
—, reaction with aniline hydrochloride, 614
—, — formaldehyde, 625
—, — hydrogen bromide, 318
—, — hydrogen chloride, 311

Styrene, reaction with phenol, 606
—, — toluidine, 614
β-Styrylacrylic acid anhydride, from ketene-cinnamic aldehyde reaction, 439
Submerged combustion, 1061
Succinic acid, catalyst, hydrogenation of olefins, 900
—, from acetylene hydrocarbons, 904
—, from cyclopentane, 876
—, from dibromocyclobutane, 763
—, from maleic acid, 945
—, from paraffin wax, 971
—, solubility of, 959
Succinic anhydride, as antioxidant, 941
—, reaction with thionyl chloride, 945
Succinimide, antioxidant, cracked hydrocarbons, 915
Succinyl peroxide, catalyst, hydrogenation of olefins, 900
Sucrose, 2,3-butene glycol from, 547
Sulphate-bearing waters, reduction by oils, 48
Sulphates, as demulsifying agents, 1085, 1086
—, as detergents, 1073, 1074, 1082-1086
—, as emulsifying agents, 1085, 1086
—, as wetting agents, 1085, 1086
—, from aliphatic acids, 1086
—, from coconut oils, 1084
—, from paraffin wax, 1086
—, in de-inking paper, 1086
—, in shaving preparations, 1081
—, metallic, hydration catalysts, 288
Sulphinic esters, from ethylene, 617
Sulphites, reaction with olefins, 616
Sulphoaromatic stearic acids, catalysts, absorption of propene by sulphuric acid, 358
Sulphobutyric acid, preparation of, 819
β-sulphoethylsulphones, from vinyl sulphones, 618
Sulphonal, preparation from mercaptol, 822
Sulphonated naphthenic acids, as dyes, 1117, 1118
—, in cleaning agents, 1112, 1118
Sulphonated oil, in brake fluid mixtures, 539
Sulphonates, as detergents, 1082-1086
—, as dust fixatives, 1079
—, as emulsifying agents, 1219
—, as siccatives, 1081
—, as tanning agents, 1078
—, classification, 1065
—, from alkyl halides, 804
—, in fungicides, 1078
—, in insecticides, 1078
—, in medicinal preparations, 1080
—, in polishing compositions, 1079
—, in rubber compounding, 1078
—, in shaving preparations, 1081
—, refining with ammonia, 1072, 1073
—, separation of, 1065, 1072, 1073
—, solubility of, 1065
Sulphones, from butadiene homologues, 694-696
—, from olefins, 616, 617
—, from thioethers, 479, 480
Sulphonic acids, as adsorbents, 1080
—, as demulsifying agents, 1074, 1075, 1116
—, as detergents, 1073, 1074
—, as emulsifying agents, 1074, 1075
—, as hydrolyzing agents, 1069
—, as insecticides, 1077, 1078
—, as wetting agents, 1075-1077
—, catalysts, cracking, 114
—, —, dehydration of hydroxy-acids, 968
—, —, esterification of alcohols, 1080, 1081
—, —, reaction of isopropyl alcohol and acetic acid, 376
—, — reaction of propene and sulphuric acid, 358
—, effect of naphthenic acids on, 1069
—, estimation of, 1065
—, from aromatics, 1065
—, from cracked distillates, 1075, 1076
—, from halogenated hydrocarbons, 819, 820
—, from mineral oils, 1074, 1076
—, from olefins, 616
—, from petrolatum, 1069
—, from petroleum distillates, 1069, 1076
—, from shale-oil tar, 1069
—, from sulphurated paraffins, 1083
—, from sulphur dioxide extract, 1076
Sulphonic acids, from thiosulphates, 1083
—, hydrolysis of, 1081
—, in coagulation of carbon, 1081
—, in refining gasoline, 670
—, in treating textiles, 1075-1077
—, properties of, 1064-1068
—, reaction with aldehydes, 1081
—, — aromatic amines, 1068
—, — benzotrichloride, 794
—, — ferric salts, 1065
—, — mercaptans, 472
—, — olefins, 393
—, resins from, 1081
—, separation of, 1065, 1070-1073
Sulphonyl chloride, promoter, bromination of benzene, 790, 791
—, reaction with *o*-dichlorobenzene, 782
Sulphoricinoleic acid, catalyst, sulphation of ethylene, 323
—, —, sulphation of propene, 358
Sulphovinic acid, formation of, 320
Sulphoxides, from thioethers, 479, 480
Sulphur, as heat-transfer medium, 861
—, catalyst, amines from acetone, 428
—, —, bromination of benzene, 790, 791
—, —, chlorination of toluene, 793
—, —, pyrolysis of benzene, 192
—, —, — paraffins, 158
—, colloidal, preparation of, 467, 468
—, corrosive action of, 466
—, effect on catalysts in Kogasin synthesis, 1236
—, — color stability, 455
—, — light stability, 924
—, — pyrolysis of methane, 54
—, estimation of, 1127, 1128, 1156, 1157, 1160-1163
—, from hydrogen sulphide, 460, 461
—, in fungicides, 1078
—, inhibitor, polymerization of chloroprene, 681
—, in insecticides, 1114
—, in lubricants, 469, 486, 1116
—, in petroleum, 454
—, mercaptans from, 1157
—, reaction with acetonaphthone, 469
—, — acetylene, 467, 485, 720
—, — asphalt oil, 467
—, — benzene, 468
—, — benzophenone, 468
—, — carbon tetrachloride, 469
—, — cracked distillates, 467
—, — hydrocarbon oils, 467, 468
—, — hydrogen, 1157
—, — mercaptans, 470
—, — mercury, 1156
—, — potassamide, 469
—, — saturates, 455, 456, 1102
—, — unsaturates, 455, 456, 467, 468
—, removal by alkalies, 115, 489, 1249
—, — alkali polysulphides, 467
—, — brass, 397
—, — cobalt oxide, 397
—, — dichloroethane, 745
—, — halogenation, 490
—, — hydrogenation, 115, 964, 1248, 1249
—, — iron oxide, 1248, 1249
—, — iron sulphide, 397
—, — metallic compounds, 488, 489
—, — oxidation, 489, 490, 964, 1043, 1044
—, — phenol, 134
Sulphurated paraffins, sulphonic acids from, 1083
Sulphur chloride, catalyst, chlorination of ethylene, 495
—, —, — propene, 507
—, in estimation of lead tetraethyl, 1165
—, reaction with diolefins and oxygen, 696
—, — ethylene and sodium polysulphide, 618, 619
—, — mercaptans, 481
—, — olefins, 618, 619
—, — saturated hydrocarbons, 1102
—, refining agent, gasoline, 929
Sulphur compounds, autoxidation of, 905
—, corrosion by, 456
—, decomposition by bacteria, 490
—, effect of distillation on, 11

Sulphur compounds, effect on asphaltene formation, 1190
—, — color stability, 454-456
—, — lead susceptibility, 456
—, — light stability, 924
—, in crude oils, 11, 12, 17
—, in gases, estimation of, 1125
—, inhibitors, polymerization of chloroprene, 681
Sulphur content, of commercial propane, 25
—, of petroleum, 454
—, reduced during aquolysis, 133
Sulphur dichloride, carbon tetrachloride from, 730
Sulphur dioxide, effect on ethylene polymerization, 639
—, estimation of, 1125
—, extraction agent, acetylene, 169
—, — aromatics, 30, 35, 36
—, — naphthenic acids, 1107
—, — nitrogen bases, 832, 838

Temperature-entropy relations, 1335-1341
Temperature-pressure-enthalpy relations, 1332-1335
Temperature-volume-pressure data, correlation, 1320-1322
Terpenes, as antiknocks, 1017
—, by diene reaction, 688
—, from carbon monoxide and hydrogen, 1244
—, from coniferous wood, 46
Terephthalyl chloride, reaction with isopropyl hydroperoxide, 382
Terpineol, as antiknock, 1017
—, as blending agent, 1035
—, reaction with formaldehyde, 624
Tertiary alcohols, condensation with phenols, 416
—, dehydration of, 410
—, esters of, 412
—, ethers from, 413
—, from ketones, 452
—, oxidation of, 410
—, reaction with aromatics, 411
—, — phenols, 412
Tertiary alkyl hypohalites, preparation of, 418
Tertiary olefins, from tertiary alcohols, 410
—, reaction with hydrogen halides, 310
—, — ethylene glycol, 544
—, separation from secondary olefins, 314
Tetra-alkylphenols, antioxidants for gasoline, 916
Tetrabromobenzene, from benzene, 790, 791
Tetrabromocyclobutane, preparation of, 763
Tetrabromocyclohexane, preparation of, 770
Tetrabromocyclohexanone, preparation of, 770
Tetrabromoethane, preparation of, 747
Tetrabromopentane, from amylene, 513
1,2,4,5-Tetrachlorobenzene from dichlorobenzenes, 781
Tetrachlorobutadiene, from butadiene, 685
Tetrachlorobutane, preparation of, 811
—, 2,3-dichlorobutadiene from, 686, 687
Tetrachlorocyclopentane, preparation of, 763
Tetrachloroethane, as cooling medium, 746
—, dechlorination of, 805
—, from carbon tetrachloride, 731
—, in cleaning fluids, 746
—, in insecticides, 747
—, in manufacture of films, 746
—, reaction with sulphuric acid, 746, 829
—, stabilization of, 743
Tetrachloroethylene, purification of, 745
Tetrachloromethane, *see* Carbon tetrachloride
Tetrachloropentane, formation of, 511
Tetrachloropyrene, oxidation of, 956
Tetracosene, from isobutene, 643
Tetradecane, cracking of, 100, 101, 1297
—, —, free energy change, 1297
—, from di-*n*-heptyl mercury, 71
Tetradecene, in kerosene, 145
Tetraethylene glycol, from ethylene oxide, 557
Tetraethanol ammonium hydroxide, preparation of, 572
Tetraethyl lead, *see* Lead tetraethyl
Tetrahexacontane, synthesis of, 40
Tetrahydrobenzene, from cyclohexane, 93
Tetrahydrofurfuryl alcohol, as extraction agent, 44
Tetrahydronaphthalene, corrosion inhibitor, 477
—, in dewaxing lubricants, 433
—, in motor fuel, 1039
—, reaction with chlorinated Kogasin, 1253, 1254
—, — ethylene, 594
Tetrahydro-α-naphthol, from tetralin peroxide, 906
1,2,4,5-Tetraisopropylbenzene, synthesis of, 382
Tetraisopropyl hydroferrocyanate, antiknock, 1018
Tetralin, absorbent for butadiene, 174
—, autoxidation of, 905, 906
—, ethylation of, 209, 210
—, preparation of, 649
Tetralin peroxide, as antiknock, 1017, 1018
—, formation of, 905
—, reaction with iron carbonyl, 906

Tetralin peroxide, reaction with potassium permanganate, 905
—, reduction of, 906
Tetramethylbenzene, from petroleum, 35
1,2,3,4-Tetramethyl-1,3-butadiene, from methylethylpinacone, 678
Tetramethylethylene, dinitrate from, 621, 622
—, dinitrite from, 621
—, from di-*ter*-butylethylene, 87, 411, 645
—, nitro-nitrate from, 621, 622
—, polymerization of, 643, 645
—, reaction with nitrogen tetroxide, 621
—,1,1,2-trimethyl propanol from, 388
Tetramethylene bromide, reaction with mercaptans, 485
Tetramethylethylene chlorohydrin, preparation of, 520
3,4,5,5-Tetramethylhexene-2, from 1,2-dimethylpropanol-1, 400
Tetramethylmethane, *see* Neopentane
2,2,3,4-Tetramethylpentanol-3, dehydration of, 411
2,2,4,4-Tetramethylpentanol-3, dehydration of, 401
1,2,3,3-Tetramethylpentene-2, synthesis of, 411
2,3,4,4-Tetramethylpentene-2, synthesis of, 411
Tetranitromethane, synthesis of, 1090
Tetranitromethylaniline, as antiknock, 1017
Tetrasulphides, preparation of, 481
—, use in Diesel fuels, 486
Tetryl, purification of, 496
T-gas, definition of, 556
Thallium, catalyst, chlorination of ethane, 741
Thallium alkyls, as antiknocks, 1018
Thallium aryls, as antiknocks, 1018
Thallium halides, catalyst, dehydrogenation of hydrocarbons, 158
Thallium oxide, catalyst, oxidation of aromatics, 942
—, catalyst, oxidation of pinene, 905
Thermatomic process, for carbon black, 219, 220
Thermax carbon black, 235
Thermodynamic variables, engineering, definitions of, 1306, 1307
—, units of, 1272
Thermodynamics, application to petroleum technology, 99
—, limitations of, 1276, 1295-1297
—, nomenclature, 1272, 1273
—, of cracking, 99
—, third law of, 1277
Thianthrene, from benzene, 468
Thioacetaldehyde, from acetylene, 720
Thioalcohols, reaction with ketene, 438
Thiocarbamides, for stabilizing carbon tetrachloride, 730, 731
Thiocarbonates, preparation of, 487
Thiocresol, reaction with acetylene, 473
—, — divinylacetylene, 709
—, — formaldehyde, 473, 474
Thiocyanates, extraction agents, 44
Thiocyanogen, preparation of, 629
—, — butadiene, 698
—, — olefins, 629, 1152, 1153
Thiodiarylamines, antioxidants for gasoline, 918
Thiodiethylene glycol, formation of, 564
Thioethers, boiling points of, 479
—, effect on lead susceptibility, 1031
—, from mercaptans, 472, 473, 479
—, heats of vaporization, 479
—, in petroleum, 454
—, oxidation of, 479, 480
—, reaction with ammonia and sulphur, 481
—, — mercuric chloride, 479
—, solvents for rubber, 486
Thioethylene glycol, from ethylene oxide, 563
Thioindigo, preparation of, 469
Thicnaphthene, from acetylene, 720
Thionylaniline, reaction with mercaptans, 481
Thionyl chloride, reaction with alcohols, 413
—, — acid anhydrides, 945
—, — cyclohexane, 1102
—, — 1,4-cyclohexanediol, 766
—, — cyclohexanol, 766

Thiophenol, estimation with sodium nitroprusside, 1159, 1160
—, from chlorobenzene, 785
—, separation from phenols, 476
Thiophthene, preparation of, 467, 484, 485, 720
Thiophthene, properties of, 484
Thiosulphates, oxidation of, 1083
—, reaction with alkyl halides, 829
—, sulphonic acids from, 1083
Thiourea, in fungicides, 569
—, in synthetic resins, 890
—, reaction with amines, 587
—, — ethylene oxide, 564
Thiuram disulphide, inhibitor, polymerization of chloroprene, 681
Thoria, catalyst, decomposition of ether, 335
—, —, dehydration of alcohols, 399
—, —, dehydration of glycol ethers, 174
—, —, dehydrogenation of paraffins, 159
—, —, esterification of alcohol, 339
—, —, ether from ethyl alcohol, 331
—, —, hydration of ethylene, 289
—, —, isomerization of propene oxide, 586
—, —, methane-steam reaction, 272, 278
—, —, oxidation of ethylene, 553
—, —, pyrolysis of olefins, 190
—, —, — oxygenated hydrocarbons, 340
—, —, reduction of carbon monoxide, 1228, 1235, 1236, 1237, 1240
Thoria aerogel, catalyst, pyrolysis of propionic acid, 446
Thorium, catalyst, pyrolysis of acetals, 715
—, promoter, oxidation of methyl alcohol, 878, 879
—, —, reduction of carbon monoxide, 1228, 1229, 1230, 1232, 1236, 1249, 1250
Thorium compounds, catalysts, acetylene-ammonia reaction, 719
Thorium dioxide, catalyst, cracking of petroleum, 111
—, —, reduction of carbon monoxide, 1228, 1229
Thorium oxide, catalyst, dechlorination of propyl chloride, 805
—, —, decomposition of acids to ketones, 443, 446
—, —, hydration of acetylene, 714
—, —, hydration of glycols, 548
—, —, hydrogen-carbon monoxide reaction, 661
—, —, hydrolysis of chlorobenzene, 782
—, —, methane-steam reaction, 270, 278, 279
—, —, nitration of paraffins, 1091
—, —, oxidation of aromatics, 942
—, —, oxidation of hydrocarbons, 850, 851
—, —, — methyl alcohol, 878
—, —, production of biphenyl, 192
—, —, pyrolysis of isobutyl bromide, 806
—, —, — mesityl oxide, 423
—, —, reaction of amines and alcohols, 614
Thorium nitrate, promoter, reduction of carbon monoxide, 1232
Thymol, reaction with isoamylene, 606
Thymol monosulphide, as antioxidant, 941
Time factor, in cracking, 105, 139
Time-temperature index, use of, 105, 106
Tin, alloys of, in cracking, 113
Tin, antioxidant, for insulating oils, 939
—, catalyst, oxidation of ethylene, 552
—, —, — lubricants, 933
—, —, — naphthenes, 939, 940
—, —, — paraffins, 660

Tin, catalyst, polymerization of olefins, 665
—, —, pyrolysis of hydrocarbons, 160, 189, 191
—, effect on sludge formation, 939
—, use in refining gasoline, 668
Tin chloride, catalyst, chlorination of ethylene, 495
—, —, — propene, 507
—, —, ether from ethyl alcohol, 331
—, desulphurizing agent, 488
Tin dioxide, catalyst, decomposition of natural gas, 227
Tin halides, catalyst, dehydrogenation of hydrocarbons, 158
Tin iodide, catalyst, acetone-amine reaction, 429
Tin naphthenate, as antioxidant, 1116
Tin oleate, as antioxidant, 938
Tin oxide, catalyst, acetone from ethyl alcohol, 422
—, —, acetylene-steam reaction, 714
—, —, oxidation of aromatics, 942
—, —, — methyl alcohol, 878
—, effect on ignition temperatures, 1000
—, for hydrogen sulphide removal, 458
—, for refining gasoline, 929
Tin phosphate, catalyst, hydration of ethylene, 287
—, —, hydrolysis of methyl chloride, 727
—, —, — methylene chloride, 728
Tin ricinoleate, antioxidant for lubricants, 933
Tin tetrachloride, catalyst, polymerization of olefins, 195
—, —, preparation of gasoline, 195
Tin tetraethyl, antioxidant for lubricants, 933
Tin tetraphenyl, antioxidant for lubricants, 933, 938
Titania, catalyst, esterification of alcohol, 339
—, —, pyrolysis of propene oxide, 586
Titanic acid, promoter, pyrolysis of alcohol, 351
Titanium, use in alloys, 134
Titanium carbide, catalyst, oxidation of naphthalene, 946
Titanium chloride, catalyst, polymerization of olefins, 636, 665
—, —, preparation of gasoline, 203
—, desulphurizing agent, 488
Titanium dioxide, catalyst, cracking of petroleum, 111
Titanium halides, catalyst, dehydrogenation of hydrocarbons, 158
—, —, reaction of olefins and carbon monoxide, 625, 626
Titanium naphthenate, as wetting agent, 1117
Titanium oxide, catalyst, hydration of acetylene, 714
—, —, hydrolysis of chlorobenzene, 782
—, —, methane-steam reaction, 279
—, —, methyl alcohol-carbon monoxide reaction, 1050
—, —, oxidation of hydrogen sulphide, 460
—, —, — aromatics, 942
—, —, preparation of monovinyl acetylene, 705
—, —, pyrolysis of methane, 228
Titanium phosphate, catalyst, hydration of ethylene, 287
Titanium tetrachloride, catalyst, alkylation of aromatics, 596
—, —, polymerization of isobutene, 204, 210, 642
—, in refrigerants, 738
Toluene, acetylene from, 260
—, action of aluminum chloride on, 208
—, — silent discharge on, 260
—, — Tesla discharge on, 260
—, as antiknock, 1017
—, as blending agent, 1035
—, bromination of, 794, 795
—, by polymerization of cracking gas, 646
—, by pyrolysis of alcohol, 173, 177
—, — cylinder oil, 137
—, — gas oil, 178
—, — gasoline, 136
—, — kerosene, 137, 144
—, — natural gas, 183
—, chlorination of, 793, 794
—, coloring matter prepared from, 215
—, detection in alcohol, 354
—, for estimation of water in oils, 1168
—, for extraction of olefins, 163
Toluene, from allyltoluene, 96
—, from benzene, 206
—, from carbon monoxide and hydrogen, 1243
—, from cycloheptane, 94
—, from 2,6-dimethylanthracene, 96
—, from ethylbenzene, 96
—, from ethylcyclohexane, 93
—, from ethylene, 77, 186
—, from *n*-heptane, 73
—, from isobutene, 85
—, from pinene, 88
—, from propane, 60, 182
—, from xylene, 96, 208
—, hydrogenation of, 347
—, in dehydration of isopropyl alcohol, 364
—, inflammability limits of, 980, 981
—, in gasoline, 34, 35, 144, 196
—, in motor fuel, 1039
—, molal entropy, 1290
—, nitration of, 954, 1091
—, oxidation of, 843, 942-944, 947-950, 953, 954
—, reaction with acetic acid, 448
—, — acetylene, 718
—, — amyl alcohols, 411
—, — *sec*-butyl alcohol, 402
—, — *ter*-butyl alcohol, 411
—, — chlorinated Kogasin, 1253, 1254
—, — isopropyl alcohol, 382, 401, 402
—, — nitrosyl chloride, 794
—, — propene, 594, 596
—, toluquinone from, 953
Toluene sulphonamide, alkyl derivatives in brake fluids, 542
p-Toluenesulphonic acid, catalyst, dehydration of tertiary alcohols, 410
—, —, hydration of olefins, 297, 410
Toluidine, as antiknock, 1018
m-Toluidine, from *m*-cresol, 788
o-Toluidine, reaction with ethyl chloride, 808
—, — sulphonic acids, 1068
p-Toluidine, reaction with sulphonic acids, [illegible]
—, — styrene, 614
Toluquinone, from toluene, 953
o-Tolyl ammonium chloride, preparation [illegible]8
Tolylenediamines, antioxidants for gas[illegible]7
β-*p*-Tolylethyl alcohol, preparation of [illegible]
p-Tolyl-*β*-sulphoethylsulphone, prepa[illegible]
Tonsil, catalyst, hydrolysis of chlor[illegible]
Top oils, preparation of, 968
Total heat, definition of, 1306
—, of naphtha, 15
—, of pentane, 15
Transformer oil, antioxidants for, 941
—, oxidation of, 963
—, sludge formation in, 940
—, sulphonation of, 1065
Transition reaction, definition of, 56
Triacetin, in brake fluids, 546
—, methane from, 19
Tribromobenzene, from benzene, 791
Tribromopentane, from amylene, 513
Tri-*ter*-butylbenzene, preparation of, 592
Trichloroacetaldehyde, *see* Chloral
Trichloroacetic acid, promoter, alcohol-vinylacetylene reaction, 706
—, —, alkylation of benzene, 596
—, reaction with cyclohexene, 313
—, — ethers, 345
—, — ethylene oxide, 540
—, — isopropyl alcohol, 376
—, — propene, 308
—, — trimethylethylene, 313
Trichloracetyl chloride, reaction with methoxymethanol, 541
Trichloroacetyl glycol, preparation of, 540
—, reaction with acetyl chloride, 541
—, — ammonia, 541
—, — diazomethane, 540
—, — ethyl alcohol, 541
—, — thionyl chloride, 541
—, structure of, 540, 541
Trichloroacetyl glycol methyl ether, preparation of, 541
—, reaction with ethyl alcohol, 541
Trichlorobenzene, in dielectrics, 789

1,2,4-Trichlorobenzene, in lubricating oil, 790
Trichlorobenzyl chloride, reaction with benzene, 816
Trichlorobutane, preparation of, 811
Trichloro-*ter*-butyl alcohol, from chloroisobutene, 522
1,2,3-Trichloro-2-chloromethylbutane, formation of, 513
Trichlorocyclopentane, preparation of, 763
Trichlorocyclopropane, formation of, 761
Trichlorodiphenylmethane, as transformer oil, 816
—, preparation of, 816
Trichloroethane, fluorodichloroethane from, 747
—, from ethylene dichloride, 501
—, from vinyl chloride, 716
Trichloroethylene, action of light on, 710
—, as anesthetic, 711
—, as solvent, 710
—, corrosive action of, 710, 711
—, decaffeination agent, 710
—, detection of, 710
—, for dewaxing oils, 710
—, from acetylene tetrachloride, 710
—, in alcohol distillation, 327, 328
—, in insecticides, 747
—, separation of acids with, 967, 968
—, stabilization of, 328, 710
—, toxicity of, 710
Trichlorofluoromethane, from carbon disulphide, 737
—, from carbon tetrachloride, 734
Trichloromercuriacetaldehyde, formation of, 702
Trichloromethane, *see* Chloroform.
1,2,3-Trichloro-2-methylbutane, formation of, 513
1,2,3-Trichloro-2-methylpropane, hydrolysis of, 797, 798
Trichloropentane, formation of, 511, 512
Trichloropropane, preparation of, 506
—, as cleaning agent, 751
1,1,2-Trichloropropane, from propene dichloride, 508
1,2,3-Trichloropropane, from propene dichloride, 507, 508
Trichlorotrifluorobenzene, as solvent, 792
Trichlorotrifluoroethane, diluent, fluorination of benzene, 792
n-Tridecane, reaction with benzene, 1254
Tridecene, from tetradecane, 100
—, in kerosene, 145
Tridecylxylene, preparation of, 1254
Tri-(2,5-dichlorophenyl) methane, from dichlorobenzene, 729
Triethanolamine, as pour depressant, 577
—, dehydration agent, 538, 578
—, estimation of, 572
—, inhibitor of gum formation, 915
—, miscellaneous uses of, 575-576
—, preparation of, 567
—, reaction with carbon dioxide, 578
—, — fluorochloromethanes, 737
—, — metallic salts, 570-572
—, — trinitrotoluene, 570
—, — wood rosin, 578
—, removal of hydrogen sulphide by; 458, 574, 575
—, use in decarbonizing, 790
—, — electrodeposition of metals, 571
—, — ethylene dichloride-sodium polysulphide reaction, 499
—, — ethylene oxide-benzene reaction, 563
Triethanolamine bicarbonate, for carbon dioxide removal, 574
Triethanolamine hydrochloride, solubility in alcohols, 568
Triethanolamine hydroxyabietate, preparation of, 578
Triethanolamine lactate, uses for, 578
Triethanolamine oleate, in emulsifying agents, 1074, 1217
—, in wetting agents, 1076
Triethanolamine soaps, uses of, 575, 576
Triethylamine, stabilizing agent, 328
Triethylbenzene, from ethylbenzene, 208
Triethyl carbinol, from diethyl ketone, 452
Triethylene glycol, from glycol, 557
Triethylene glycol propionate, in cellulose compositions, 546
Triethylethylene, from isobutene, 85
Triethylmethane, in motor fuel, 501, 1039
—, oxidation of, 876
Triethylolsulphonium hydroxide, preparation of, 564
Trifluorotrichloroethane, preparation of, 735
Trihydroxyethyl sorbite, reaction with isopropyl urea, 587
Triisobutylene, from isobutene, 591, 642
—, reaction with benzene, 592
—, — hydrogen chloride, 311
—, — phenol, 605
Triisopropanolamine, preparation of, 587
Triisopropylbenzene, preparation of, 382
Triisopropyltoluene, preparation of, 382
Trimethylacetic acid, from acetone, 432
—, from *n*-butane-carbon monoxide reaction, 1100
—, from 2-butene, 626
—, *see also* Pivalic acid
Trimethylbenzene, in petroleum, 34, 35
—, molal entropy, 1290
—, *see also* Pseudocumene
2,2,3-Trimethylbutane, molal entropy, 1292, 1293
Trimethylcarbinol, *see also* *ter*-Butyl alcohol
1,1,4-Trimethylcycloheptane, pyrolysis of, 94
1,1,4-Trimethylcycloheptene, dehydrogenation of, 94
—, isophthalic acid from, 94
Trimethylcyclohexane, in petroleum, 34
—, chlorination of, 775, 776
Trimethylene, extraction agent, 44
Trimethylene glycol, reaction with 2,3-dichloro-1,4-dioxane, 549
Trimethylene glycol diacetate, as solvent, 549
Trimethylene mercaptan, reaction with methylene chloride, 485
—, tetramethylene bromide, 485
Trimethylethylene, *ter*-amyl alcohol from, 387, 391
—, *ter*-amyl nitrate from, 623
—, co-polymerization with hexadiene, 216
—, from 2,2,4,4-tetramethylpentanol-3, 401
—, glycols from, 547, 895
—, in gasoline, 144
—, polymers of, 203, 210, 633
—, reaction with chlorine, 513
—, — hydrogen chloride, 310
—, — hydrogen peroxide, 547
—, — nitric acid, 623
—, — nitric acid and amyl nitrite, 621
—, — nitrogen pentoxide, 621
—, — nitrogen tetroxide, 621
—, — sulphuric acid, 308, 391
—, — trichloroacetic acid, 313
—, *see also* Isoamylene and 2-Methyl-2-butene
Trimethylethylene bromide, glycol from, 547
Trimethylethylene chlorohydrin, preparation of, 520
Trimethylethylene glycol, preparation of, 895
3,5,5-Trimethylheptene-2, from 1,2-dimethylpropanol-1, 400
2,2,4-Trimethylhexene-2, preparation of, 411
3,3,5-Trimethylhexene-2, preparation of, 411
2,4,4-Trimethylhexene-3, preparation of, 411
Trimethylmethane, in motor fuel, 501, 1039
2,2,4-Trimethylpentane, action of aluminum chloride on, 199-201
—, formation of, 417
—, isomers, molal entropy of, 1289
—, reaction with benzene, 602, 603
—, — ethylene, 599
—, *see also* Isooctane
2,4,4,-Trimethyl-2-pentene, pyrolysis of, 87
1,1,2-Trimethylpropanol, from tetramethylethylene, 388
Trimethylpyridine, preparation of, 719
2,3,8-Trimethylquinoline, from petroleum, 834
Trinidad asphalt water-white hydrocarbons from, 1187
Trinitrophenol, estimation of aromatics with, 1154, 1155
Trinitrotoluene, reaction with diethanolamine, 570
—, separation from dinitrotoluene, 496

Triphenylamine, preparation of, 787, 810
Triphenyl bismuth, antioxidant for lubricants, 938
Triphenylcarbinol, from triphenylmethane, 957
Triphenylchloromethane, reaction with cyclohexadiene, 694
Triphenylene, from cyclohexanone, 451
Triphenylethane, from stilbene, 207
Triphenylethylene, reaction with ozone, 902
Triphenylmethane, molal entropy, 1289
—, oxidation of, 943, 957
Triphenyl phosphate, antioxidant for gasoline, 917
Triple point, definition of, 743
Tripropanolamine, reaction with cobalt chloride, 587
Trisodium phosphate, catalyst, dehydration of 1,3-butene glycol, 174
—, emulsifier for asphalts, 1217-1219
sym-Trithiane, from formaldehyde, 463
Trouton's law, defined, 479
Tube and Tank process, for cracking, 117
Tungsten, catalyst, hydration of ethylene, 291
—, —, pyrolysis of acetals, 715
—, —, — paraffins, 160, 169, 189
—, —, reaction of butene with sulphuric acid, 387
—, in cracking, 114
—, in preparation of amines, 428
—, promoter, oxidation of methyl alcohol, 879
—, —, — toluene, 949
Tungsten carbonate, catalyst, oxidation of methane, 881
Tungsten compounds, catalyst, acetylene-ammonia reaction, 719
—, —, olefin-carbon monoxide reaction, 626
Tungsten halides, catalyst, dehydrogenation of hydrocarbons, 158
Tungsten oxide, catalyst, aromatics from paraffins, 189
—, —, cracking of ethylbenzene, 159
—, —, cracking of heavy oils, 115
—, —, dehydrogenation of paraffins, 158
—, —, hydration of acetylene, 712
—, —, hydrolysis of chlorobenzene, 782
—, —, methane-steam reaction, 279
—, —, methanol-carbon monoxide reaction, 1050
—, —, nitration of toluene, 954
—, —, oxidation of aromatics, 942, 945
—, —, — hydrogen sulphide, 460
—, —, — methane, 881
—, —, pyrolysis of benzene, 192
—, —, — methane, 228
—, —, reaction of amines and alcohols, 614
—, —, reduction of carbon monoxide, 1228
Tungsten salts, catalyst, oxidation of olefins, 894
—, —, propene absorption by sulphuric acid, 357
Tungstic acid, catalyst, hydration of acetylene, 712
—, —, — ethylene, 288-291
—, —, methanol-carbon monoxide reaction, 1050
Tungstic acid salts, catalyst, hydration of ethylene, 288
Tungstic sulphide, catalyst, hydration of acetylene, 712
Turkey-red oil, promoter, ethyl alcohol from ether, 333
Turpentine, absorbent for butadiene, 174
Turpentine, autoxidation of, 905
T.V.P. process, of cracking, 122

U

Ultraviolet absorption, change in, 15
Ultraviolet light, action on acetylene, 266, 703
—, effect on decalin autoxidation, 907
—, — gum formation, 922, 924
—, — nitration of paraffins, 1091
—, — peroxide formation, 922
—, in chlorination of ethane, 741
—, in estimating gum in gasoline, 910
Undecane, from carbon monoxide and hydrogen, 1243
Undecene, in gasoline, 144
—, in kerosene, 145
Undecenoic acid, reaction with hydrogen bromide, 318
—, — hydrogen fluoride, 307
Undecyl ketol, preparation of, 443
Unimolecular law, in cracking of hydrocarbons, 102
Unsaponifiable substances, adsorption by silica, 732
Unsaturates, bromination of, 1150
—, effect of lead tetraethyl on, 1019
—, estimation, by hydrogenation, 1153, 1154
—, —, in gasoline, 1150
—, —, with bromine, 1150, 1152
—, —, with iodine, 1152
—, —, with iodine bromide, 1152
—, —, with iodine chloride, 1152
—, —, with thiocyanogen, 1152, 1153
—, from wax acids, 979
—, reaction with Kattwinkel's reagent, 1150
—, — platinic halides, 628
—, — sulphuric acid, 1150
—, *see also* Olefins
Unsaturation, effect on viscosity, 37
Urania, promoter, esterification of alcohol, 339
Uranic salts, catalyst, oxidation of ethylene, 894
—, —, hydration of acetylene, 712
Uranium, acid salts, catalyst, olefin-carbon monoxide reaction, 626
—. catalyst, reaction of butene with sulphuric acid, 387
—, promoter, oxidation of methyl alcohol, 878
—, —, reduction of carbon monoxide, 1228, 1229, 1230
Uranium boro-phosphate, catalyst, hydration of propene, 292
Uranium chloride, as antiknock, 1018
—. catalyst, polymerization of isobutene, 204
Uranium fluoride, catalyst, cyclization of aliphatic hydrocarbons, 74
Uranium halides, catalyst, dehydrogenation of hydrocarbons, 158
Uranium molybdate, catalyst, oxidation of toluene, 948
Uranium oxide, catalyst, cracking of ethylbenzene, 159
—, —, cyclization of aliphatic hydrocarbons, 74
—, —, dehydration of alcohols, 420
—, —, oxidation of aromatics, 942
—, —, — gas oil, 863
—, —, — kerosene, 966
—, —, — methane, 871
—, —, polymerization of acetylene, 705
—, —, pyrolysis of oxygenated hydrocarbons, 340
—, effect on ignition temperatures, 1000
—, promoter, reduction of carbon monoxide, 1228
Uranium phosphate, catalyst, hydration of ethylene, 284
—, —, — propene, 292
Uranium salts, catalyst, sulphation of propene, 357
Uranium tungstate, catalyst, oxidation of toluene, 948
Uranous-uranic oxide, promoter, reduction of carbon monoxide, 1229
Uranyl oxide, catalyst, cracking of petroleum, 111
Urea, as antiknock, 1018
—, color stabilizer for gasoline, 926
—, in detergents, 1073
—, in fungicides, 569
—, in synthetic plastics, 890
—, reaction with amines, 587
—, — ethylene chlorohydrin, 525
—, — monoethanolamine, 569
Ureides, stabilizers for carbon tetrachloride, 730, 731
Urethans, inhibitors, gum formation, 915
—, preparation of, 569
Useful work, definition of, 1275
Utah wax, oxidation of, 1057
Uvitic acid, from mesitylene, 954

V

Vacuum distillation, effect on corrosive sulphur, 11
Valeric acid, from *n*-amylsulphonic acid, 1067
—, from butylacetylene, 903
—, from paraffin wax, 971
γ-Valero-lactone, solvent for acetylene, 169
Vanadic acid salts, catalyst, hydration of ethylene, 288

Vanadic ions, catalyst, nitration of toluene, 954
Vanadic oxide, catalyst, oxidation of butyl alcohol, 880
—, —, — cracking gas, 881
—, —, — fluorene, 954
—, —, — kerosene, 946, 1047
Vanadium, acid salts, catalyst, olefin-carbon monoxide reaction, 626
—, catalyst, esterification of propene, 307
—, —, hydration of ethylene, 291
—, —, oxidation of ethane, 872
—, —, — methane, 869
—, —, reaction of butene with sulphuric acid, 387
—, in asphalt, 47
—, in asphaltite, 46
—, in lignite, 47
—, in petroleum, 46, 47
—, in shale, 47
—, promoter, oxidation of methyl alcohol, 879
—, use in cracking, 114, 128
Vanadium carbonate, catalyst, oxidation of methane, 881
Vanadium chloride, as antiknock, 1018
Vanadium compounds, effect on stability of lubricants, 938
—, use in acetylene-ammonia reaction, 719
—, — purification of isopropyl alcohol, 365
Vanadium halides, catalyst, dehydrogenation of hydrocarbons, 158
—, —, dichloroethane-hydrogen fluoride reaction, 747
Vanadium oxide, catalyst, cyclization of paraffins, 189
—, —, dehydrogenation of hydroaromatic hydrocarbons, 186
—, —, hydration of acetylene, 713
—, —, hydrogen-carbon reaction, 661
—, —, oxidation of anthracene, 952
—, —, — aromatics, 942, 945, 946, 949, 950
—, —, — gas oil, 863
—, —, — gasoline, 1046
—, —, — hydrogen sulphide, 460
—, —, — methane, 881
—, —, — methyl alcohol, 878
—, effect on ignition temperature, 1000
Vanadium pentoxide, catalyst, oxidation of acenaphthene, 946
—, —, — benzene, 944, 945
—, —, — furfuraldehyde, 945
—, —, — kerosene, 965, 966
—, —, — naphthalene, 946
—, —, — paraffins, 844, 850, 851, 862
—, —, — pentane, 859, 860
—, —, paraffin-nitric oxide reaction, 1091
Vanadium salts, catalyst, sulphation of propene, 357
—, —, oxidation of toluene, 950
Vanadium sulphides, in petroleum, 20
Vanadyl sulphate, catalyst, oxidation of phenylisopropenylcarbinol, 444
Vanillin, for estimation of acetone, 424
Vaporization heat, determination, 1325, 1327
—, —, from boiling point, 1325, 1327
—, —, from characterization factor, 1327
—, —, from molecular weight, 1325, 1327
Vapor-liquid phase cracking, 115
Vapor-phase cracking, 115
—, gases from, 140
—, silent discharge in, 263
Vapor pressure, critical pressure from, 1314, 1315, 1316, 1318
—, of gasoline, determination of, 1169
Vapor-recovery gasoline, octane number of, 1033
Varnishes, preparation of, 728
—, use of asphalts in, 1192
—, use of pentaerythritol esters in, 1055
Varnish remover, preparation of, 790
Varnish resins, preparation of, 1098
Vaseline, fractions of, 40
Vat dyes, ethylenediamine solvent for, 809
Vegetable oil, motor fuel from, 136
Velocity, dissociation of isobutane, 66
—, of cracking reaction, 102
Velocity constant, formation of acetylene from methane, 53
—, — ethylene from methane, 53
Veratryl alcohol, preparation of, 958
Verbenol, from pinene, 905
Verbenone, from pinene, 905
Vinethene, definition of, 529
Vinyl acetate, ethylene oxide from, 553
—, formation of, 717
—, reaction with hydrogen chloride, 718
Vinylacetic acid, reaction with ozone, 902
Vinylacetylene, 1,2-dichlorobutadiene from, 687
—, from acetylene, 680, 704
—, from dichlorobutenes, 685
—, reaction with alkaline hypohalites, 687, 706
—, — alcohol, 705, 706
—, — carboxylic acids, 706
—, — a-chloroethers, 707
—, — Grignard reagents, 708
—, — hydrogen chloride, 680, 706
—, — hydrogen sulphide-sulphur mixture, 709
—, — mercuric salts, 708
—, — potassium mercuri-iodide, 708
—, hydration of, 705
—, polymerization of, 685, 705
—, resin from, 685
—, styrene from, 706
Vinylacetylene acetic ester, polymerization of, 706
Vinyl alcohol, by ethylene oxidation, 896
Vinyl allyl ketone, preparation of, 709
Vinyl bromide, from ethylene dibromide, 504, 505, 533
—, reaction with hydrogen bromide, 315, 716
N-Vinylcarbazole, synthesis of, 719
Vinyl chloride, from acetylene, 716
—, from ethylene dichloride, 496, 497
—, reaction with chlorine, 716
—, — dichloroethane, 811
—, — hydrogen bromide, 315
—, — hydrogen chloride, 716
—, — hydrogen iodide, 716
Vinyl compounds, co-polymerization with chloroprene, 681, 682
Vinylcyclohexane, pyrolysis of, 93
Vinylethinylcarbinols, polymerization of, 708
Vinylethinylmagnesium bromide, reaction with acetone, 708
Vinylethyl sulphide, from acetylene and hydrogen sulphide, 720
N-Vinylindole, synthesis of, 719
Vinyl phenyl sulphide, preparation of, 472
N-Vinylpyrrole, synthesis of, 719
Vinyl radical, from propene, 75, 79
Vinyl resins, from acetylene, 253
Vinyl sulphones, reaction with bisulphites, 618
—, β-sulphoethylsulphones from, 618
Vinyl thioethers, preparation of, 472
Viscosity, characterization factor from, 1309, 1310
—, determination of, 1172-1176
—, effect of polycyclic groups, 37
—, — unsaturation on, 37
—, — silent discharge on, 210
—, of aliphatic hydrocarbons, 37
—, of asphalt, determination of, 1206, 1207
—, —, decreased with phenols, 1218
—, of asphalt emulsions, 1216
—, of crystal oil, effect of ethane, 15
—, —, — butane, 15
—, solutions of paraffins, 15
Viscosity breaking, 116
Viscosity gravity constant, 1176
Viscosity index, characterization factor from, 1309
—, determination of, 1176
—, effect of paraffinic side chain on, 38
Viscosity-temperature stability, of hydrocarbons, 37
Vistanex, definition of, 675
Voltolization, effect of air, 261
—, — hydrogen, 261
—, — nitrogen, 261
—, effect on viscosity, 253
—, of alkylated naphthalenes, 262
—, of aromatics, 261
—, of cracked tar, 262
—, of halogenated paraffins, 262

Voltolization, of hydrogenated tar, 262
—, of kerosene, 261
—, mechanism of, 261
—, of oils, 260-263
—, of olefins, 261
—, of oleic acid, 261
—, of paraffins, 261
—, of stearic acid, 261
Voltol oils, preparation of, 260-263
Volume, reduced, definition of, 1319
Volume-pressure-temperature data, correlation, 1320-1322
Vulcanization, of synthetic rubber, 674

W

Water, antioxidant, paraffin oil, 907
—, azeotropic mixture with isopropyl alcohol, 364, 368
—, carbon monoxide from, 256
—, catalyst, ethylene oxide-aminoacetaldehyde reaction, 561
—, —, styrene-hydrogen chloride reaction, 311
—, effect on asphalt formation in oils, 935
—, — gasoline-alcohol blends, 1035
—, electrical decomposition of, 256
—, estimation in asphalt emulsions, 1221
—, — gasoline, 1168
—, — lubricating oils, 1167, 1168
—, free energy of formation, 1275
—, —, effect of temperature on, 1304
—, hydrogen from, 256
—, in crude petroleum, 10
—, inhibitor, bromination of acetone, 430
—, —, formation of phosgene, 744
—, —, gum formation in gasoline, 909
—, —, olefin formation from isopropyl alcohol, 377
—, use in ethylene oxide-hydrogen sulphide reaction, 564
—, —, oxidation of ethylene, 534, 551, 552
Water gas, carbon monoxide from, 1246
—, ketones from, 268
Waterproofing agents, asphalt emulsions in, 1220
Water vapor, catalyst, bromination of ethylene, 501
—, —, pyrolysis of heptane, 154
—, diluent, carbon monoxide-methyl alcohol reaction, 1050
—, effect on ignition temperatures, 996, 997
Wax, chlorination of, 755, 757
—, chlorinated, reaction with benzene, 758
—, —, — calcium hydroxide, 759
—, —, — diphenylene oxide, 758
—, —, — naphthalene, 817
— — uses of, 758, 759
—, crystallization of, 38
—, effect of precipitating conditions on, 38
—, estimation in asphalt, 1155
—, extraction from asphalt, 1155
—, fractionation in cathode vacuum, 38
—, in ceramics, 1057
—, in paint, 147
—, in petroleum, 13
—, precipitation from oils, 45, 379, 1200, 1201
—, shoemaker's, preparation of, 1058
Wax acids, addition agents for mineral oils, 978, 979
—, aldehydes from, 979
—, as pour point depressants, 979
—, cracking of, 979
—, esterification of, 970, 975
—, from paraffin wax, 970, 971
—, in beeswax substitutes, 970
—, in detergents, 978
—, in emulsifying agents, 978
—, in films, 975
—, in gelatinizing agents, 975
—, in insecticides, 978
—, in lacquers, 975
—, in plastics, 975
—, in soap powders, 978
—, in soaps, 970
—, in softening agents, 975
—, in synthetic fats, 970
—, ketones from, 979
Wax acids, nitriles from, 979
—, pyrones from, 979
—, reaction with ammonia, 979
—, — phenols, 975
—, structure of, 977, 978
—, unsaturates from, 979
Wax alcohols, from paraffin wax, 973
—, properties of, 973
—, refining of, 973
—, use in yeast cultures, 979
Wax distillates, oxidation of, 850
Waxes, crystalline formation, 39
—, nitration of, 1092
—, oxidized, in road bitumen, 1057
—, preparation of, 1056
—, source for petroleum formation, 19
—, specific refraction of, 38
Waxing compositions, carbon tetrachloride in, 731
Wells, drilling of, 8, 9
Wetting agents, alkyl sulphates as, 1085, 1086
—, classification of, 1076
—, diethylene glycol in, 1076
—, ethylene glycol ethers as, 558
—, from aliphatic alcohols, 1076
—, from carboxylic acids, 1076
—, from chlorinated hydrocarbons, 758
—, from mercaptans, 472, 487
—, from oxidized hydrocarbons, 1061
—, from phenols, 1076
—, from tertiary alcohols, 417
—, glycerol in, 1112
—, hydroxyethyl ethers as, 558
—, isopropylnaphthalenesulphonic acid as, 954
—, naphthenic acid salts as, 1117
—, naphthenic acids in, 1112
—, naphthenic alcohols as, 1120
—, sulphonaphthenic acids as, 1118
—, sulphonic acids as, 1075-1077
—, triethanolamine in preparation of, 577, 1076
Wetting properties, of asphalts, 1213
Wild gasoline, butane from, 24
—, propane from, 24
Wood, adsorbent carbon from, 227
—, chlorination of, 227
—, waterproof with asphalt, 1220
Wood flour, use in resins, 625
Wood preservatives, copper naphthenate in, 1115
—, dichlorobenzene in, 790
—, polyglycol arsenites as, 545
Wood rosin, reaction with triethanolamine, 578
Wool, reaction with ethylene oxide, 561
Work content, relation to free energy, 1273

X

Xanthate-iodine titration, of alcohols, 371
Xanthate test, for alcohols, 355
Xenon, effect on acetylene polymerization, 267
X-ray diffraction, of carbon black, 245
—, of paraffin wax, 38
X-rays, action on gaseous hydrocarbons, 267, 268
—, action on water gas, 268
—, estimation of lead tetraethyl with, 1165
—, use, structure of polyethylene oxides, 563
Xylene, action of aluminum chloride on, 208
—, by pyrolysis of ethylene, 182, 186
—, — gas oil, 178
—, — propane, 60, 182
—, demethylation of, 208
—, detection in alcohol, 354
—, extraction agent for naphthenic acids, 1107
—, for dehydration of isopropyl alcohol, 364
—, — *sec*-butyl alcohol, 408
—, for estimation of water in oils, 1168
—, from acetylene and toluene, 719
—, in gasoline, 196
—, reaction with chlorinated Kogasin, 1253, 1254
—, — chloro-*n*-tetradecane, 1254
—, vapor pressure of, 15
m-Xylene, by isomerization of *o*-xylene, 208
—, — *p*-xylene, 208
—, by polymerization of cracking gas, 646
—, by pyrolysis of natural gas, 183
—, — pinene, 88
—, — *p*-xylene, 96

m-Xylene, from toluene, 208
—, hydrogen from, 273
—, in gasolines, 34, 144
—, in shale oil, 35
—, reaction with steam, 273
o-Xylene, by pyrolysis of octane, 73, 74
—, in gasolines, 34, 144
—, isomerization of, 208
p-Xylene, benzene from, 96
—, by polymerization of cracking gas, 646
—, by pyrolysis of cyclooctane, 94
—, — natural gas, 183
—, 2,6-dimethylanthracene from, 96
—, from 2,5-dimethylhexane, 73
—, from toluene, 208
—, in gasoline, 34
—, in motor fuel, 1039
—, isomerization of, 208
—, pyrolysis of, 96
Xylenes, molal entropy, 1289, 1290
Xylenols, antioxidant, for gasoline, 916
Xylidene, antioxidant for gasoline, 917

Y

Yeast cultures, wax alcohols for, 979
Yperite, *see* Dichlorodiethyl sulphide

Z

Zein, refining of, 496
Zeise's salt, *see* Potassium ethylene trichloroplatinate monohydrate
Zeolites, catalysts, decarboxylation of phthalic anhydride, 951
—, —, oxidation of toluene, 949
Zero order reaction, definition of, 501
Zinc, activator, in ethylene oxidation, 553
—, alloys of, use in cracking, 113
—, catalyst, condensation of acetone, 429
—, —, conversion of acetaldehyde to acetone, 423
—, —, — ethylene to butadiene, 172
—, —, dehydrogenation of alcohol, 1051
—, —, oxidation of methane, 881
—, —, — petroleum, 964
—, —, polymerization of olefins, 665
—, —, pyrolysis of alcohol, 350
—, —, — ethylbenzene, 159
—, —, — methane, 158, 257
—, —, rubber compounding, 250
—, effect on chlorinated hydrocarbons, 730, 782
—, inhibitor, deterioration of ethylene oxide, 554
—, nitrocyclohexane reduced by, 1095
—, 2-nitrohexane reduced by, 1094
—, promoter, oxidation of methyl alcohol, 879
—, promoter, reaction of aldehydes and cracked distillates, 625
—, reaction with trichloroethylene, 711
—, use in cracking, 114
—, — dehydrogenation of *sec*-pentanol, 443
—, — preparation of ethers, 715
—, — refining gasoline, 668
Zinc acetate, catalyst, acetylene-acetic acid reaction, 717
—, —, reaction of acetylene and hydrogen sulphide, 472
—, —, — olefin oxides and cellulose, 588
Zinc antimonides, catalysts, dehydrogenation of alcohols, 419
Zinc arsenides, catalysts, dehydrogenation of alcohols, 419
Zinc bismuthates, catalysts, dehydrogenation of alcohols, 419
Zinc bromide, catalyst, esterification of propene, 308, 316
Zinc carbonate, in polymerization of ethylene oxide, 562
Zinc chloride, antioxidant, hydrogenated oils, 914
—, catalyst, alkylation of acid halides, 611
—, —, alkylation of alcohols, 606
—, —, alkylation of phenols, 383, 403, 416, 605
—, —, cracking of oils, 112, 195
—, —, condensation of aldehydes, 886
—, —, dehydrogenation of paraffins, 158
Zinc chloride, catalyst, *p*-dioxane from acetaldehyde, 579
—, —, esterification of olefins, 304, 306, 307, 308
—, —, ether-hydrogen chloride reaction, 345
—, —, ethyl alcohol from ether, 333
—, —, fluorination of carbon tetrachloride, 734
—, —, halogenation of cyclopropane, 761
—, —, hydration of butenes, 294
—, —, — ethylene, 288
—, —, — propene, 292
—, —, hydrogenation of olefins, 670
—, —, isomerization of olefin oxides, 589
—, —, isomerization of paraffins, 72, 202
—, —, polymerization of dichlorobutenes, 685
—, —, — olefins, 195, 636, 640, 641, 642, 646
—, —, — Kogasin, 1255
—, —, preparation of phthalyl chloride, 816
—, —, reaction of alcohols and carbon monoxide, 1050
—, —, — alkyl halides and phenols, 813
—, —, — aromatics and acetylene hydrocarbons, 719
—, —, — olefin oxides and cellulose, 588
—, —, — olefins and chloroethers, 613
—, —, — phthalic anhydride and benzotrichloride, 794
—, —, — phthalic anhydride and thionyl chloride, 945
—, —, — succinic anhydride and thionyl chloride, 945
—, —, vinyl chloride-hydrogen chloride reaction, 716
—, —, voltolization, 262
—, desulphurizing agent, 434, 488
—, for dehydration of hydroxy-acids, 968
—, in aquolysis, 133
—, in dehydration of isopropyl alcohol, 364
—, promoter for activated carbon, 112
—, reaction with ethylene oxide, 560
—, — ethylenediamine, 497
—, —, isopropyl alcohol, 370
—, refining gasoline with, 909, 927-929
—, refining naphthenic acids with, 1109
—, refining of phthalic anhydride, 961
Zinc chloride-aluminum chloride, catalyst, hydration of acetylene, 714
Zinc chromate, catalyst, pyrolysis of alcohol, 352
Zinc chromate-cobalt oxide, catalyst, methane oxidation, 870
Zinc chromite, catalyst, acetone-hydrogen reaction, 432
Zinc compounds, catalyst, acetone synthesis, 714
—, —, acetylene-ammonia reaction, 719
Zinc-copper, catalyst, dehydrogenation of paraffins, 149
Zinc dust, catalyst, formation of *ter*-butyl acetate, 412
Zinc fluoride, catalyst, preparation of propyl fluoride, 307
Zinc fluoride, reaction with carbon tetrachloride, 734
Zinc halides, catalyst, dehydrogenation of hydrocarbons, 158
—, —, dichloroethane-hydrogen fluoride reaction, 747
—, —, hydration of acetylene, 712
—, —, reaction of olefins and carbon monoxide, 625, 626
—, reaction with ketones, 452
Zinc hydrogen phosphate, use in ethylene oxidation, 894
Zinc hydroxide, for hydrogen sulphide removal, 459
Zinc molybdate, catalyst, dehydrogenation of acenaphthene, 955
Zinc naphthenates, as antioxidants, 937
—, as corrosion inhibitors, 1116, 1117
—, as wetting agents, 1117
Zinc oxalate, dehydration of ethylenediamine with, 498
Zinc oxide, catalyst, acetone from acetic acid, 423
—, —, acetone from ethyl alcohol, 421
—, —, acetone-hydrogen reaction, 432
—, —, butadiene from ethyl alcohol, 173

Zinc oxide, catalyst, chlorination of benzene, 781
—, —, cracking of petroleum, 111
—, —, cyclization of aliphatic hydrocarbons, 74
—, —, dehydrogenation of acenaphthene, 955
—, —, — alcohols, 173, 420
—, —, — indenes, 95
—, —, — monoethanolamine, 568
—, — dipropyl ketone from *n*-butanol, 443
—, —, ethyl alcohol from ether, 334
—, —, hydration of acetylene, 712-714
—, —, — ethylene, 290, 191
—, —, hydrolysis of chlorobenzene, 783
—, —, ketones from ethyl alcohol, 423
—, —, olefin oxidation, 553
—, —, oxidation of aromatics, 942
—, —, — *sec*-butyl alcohol, 442
—, —, — methane, 869-871
—, —, — methyl alcohol, 878
—, —, polymerization of ethylene oxide, 562
—, —, — olefins, 665
—, —, preparation of pentaerythritol esters, 1055
—, —, pyrolysis of cyclohexane, 92
—, —, reaction of phthalic anhydride and methyl alcohol, 952
—, —, reduction of carbon monoxide, 1251, 1252
—, —, reforming of gasoline, 189
—, —, rubber compounding, 250
—, effect on ignition temperature, 1000
—, inhibitor, conversion of butene-2 to butadiene, 172
—, reaction with ethylenediamine, 497
—, refining gasoline with, 929
—, promoter, acetone from isopropyl alcohol, 420
—, —, decarboxylation of phthalic anhydride, 951
—, —, methane-steam reaction, 270
—, —, oxidation of acenaphthene, 946
—, —, — naphthalene, 946
—, —, reduction of carbon monoxide, 1228
Zinc oxide-alumina, catalyst, pyrolysis of ethylbenzene, 96
Zinc oxide-chromium oxide, catalyst, pyrolysis of paraffins, 149
Zinc oxide-manganous oxide, catalyst, acetone from acetaldehyde, 714
Zinc phosphate, catalyst, esterification of propene, 308
—, —, hydration of ethylene, 287
Zinc phosphides, catalysts, dehydrogenation of alcohols, 419
Zinc phthalate, benzaldehyde from, 952
—, benzoic acid from, 952
Zinc salts, catalyst, acids from alcohols, 1051
—, —, acetylene-phenol reaction, 715
—, —, ethylacetylene-acetic acid reaction, 718
—, —, hydration of vinylacetylene, 705
—, —, oxidation of hydrogen sulphide, 461
Zinc selenide, catalyst, dehydrogenation of alcohols, 419
—, —, hydration of acetylene, 712
Zinc stearate, catalyst, oxidation of paraffin wax, 971
Zinc sulphate, catalyst, condensation of acetaldehyde, 878
—, —, esterification of propene, 308
—, —, hydration of ethylene, 283
—, —, — propene, 292
—, in desulphurization of oils, 1044
—, in refining gasoline, 670
—, reaction with ethyl alcohol, 878
Zinc sulphide, catalyst, pyrolysis of mercaptans, 472, 479
—, desulphurizing agent, 489
Zinc tellurides, catalysts, dehydrogenation of alcohols, 419
Zirconia, catalyst, dehydration of alcohols, 399
—, —, methane-steam reaction, 272, 278
Zirconium, acid salts, catalyst, olefin-carbon monoxide reaction, 626
—, catalyst, aromatics from olefins, 189
—, —, oxidation of methane, 881
Zirconium carbide, catalyst, oxidation of naphthalene, 946
Zirconium oxide, catalyst, dechlorination of propyl chloride, 805
—, —, dehydration of diols, 548
—, —, hydrolysis of chlorobenzene, 782
—, —, methyl alcohol-carbon monoxide reaction, 1050
—, —, oxidation of aromatics, 942
—, —, preparation of monovinylacetylene, 705
—, promoter, dehydration of alcohols, 420
Zirconium salts, catalyst, oxidation of hydrocarbons, 1051
Zirconium tetrachloride, catalyst, alkylation of aromatics, 200, 596

MEMORANDA
